Dynamic approaches vary along two inversely related continua: individuality of assessment and psychometric adequacy. At one end of these continua, the assessor works in intensive, individualized interaction, modifying tasks freely, encouraging, prompting, and mediating between child and task at will to derive qualitative (as opposed to quantitative) diagnoses and educational prescriptions (Feuerstein et al., 1979). One commentator described the approach as "a clinician's dream and a psychometrician's nightmare" (Lidz, 1997). At the other end of the continua lies a test–train–retest sequence with standardized mediation and outcome measures. Mediation is delivered through a series of predetermined hints that vary from general to specific. Each hint is offered in response to the youngster's difficulty. Outcome is quantified as the number of prompts required to bring the child to correct response and as the ability to transfer to tasks other than those on which training first occurred (Campione and Brown, 1987). Some dynamic practitioners doubt the efficacy of standardized dynamic procedures, because clues are not individually modified to the child's needs (Lidz, 1997). However, the method's standard, quantifiable format renders it amenable to psychometric study.

The goals of dynamic assessment – to assess learning ability, to identify learning processes, and to teach the individual generalizable strategies for problem solving, i.e., to capitalize on cognitive plasticity (Fabio, 2005) – remain its major strength. No other assessment tradition is so ambitious. Dynamic assessment advocates have sharpened the focus of other assessment approaches, alerting them to the ultimate goal of intellectual evaluation. And in selecting response to remedial efforts as an outcome (as opposed to comparing an examinee with his or her age mates), dynamic assessors propose a powerful means of attenuating experiential bias in intelligence testing. The reasoning is as follows: Suppose there

are two children, one biologically disadvantaged with mental retardation, the other who has experienced atypical living/educational opportunities. One might expect relatively little success in teaching the child with mental retardation. However, the educationally atypical child should make great gains, i.e., there should be a large discrepancy between this youngster's pretest and posttest scores (or the child should require relatively few clues to reach problem solution), whether or not the posttest scores approximate the average test score of this child's educationally advantaged age peers. The point is that pretest scores, conceptually comparable to conventional test results, tap a different aspect of intelligence than do difference scores; pretest scores correspond to developed abilities (and, implicitly, past opportunities to develop abilities), while difference scores approximate learning potential. It is by tapping into learning potential that dynamic assessments attenuate the biases of traditional assessment.

However, research support for the claims underlying dynamic assessment is sparse, ambiguous, and often flawed. This is more the case for approaches that emphasize nonstandardized assessment than for those that stress psychometric adequacy, but weak research foundations are common to all approaches (Grigorenko and Sternberg, 1998). Little validation of the 'zone of proximal development' exists, for example, and much of what does exist has been conducted at the level of theory, ideology, and description, rather than quantitative experiment. And although change is central to the dynamic philosophy, virtually no work addresses the reliability of change scores. Little has been published on internal consistency and there is ambiguous evidence that change scores derived from different tasks do not correlate (Grigorenko and Sternberg, 1998). Although there may be reasons to expect incongruence of change scores, these reasons need to be explored and verified so that systematic predictions can be made. Questions have also been raised about variability among examiners in administering, scoring, and interpreting the less standardized assessments, and the possibility of obtaining different results for a given child as a result of this. Few studies address the issue of retest reliability of change scores, and some studies suggest that retest reliability is weak (Buchel and Schanhorst, 1993). Factor analytic studies, which are used to demonstrate that subtests intercorrelate according to theoretical expectations, are rarely conducted and do not always confirm hypotheses (Grigorenko and Sternberg, 1998). Studies have shown that mediation promotes change from pre- to posttest (Delclos et al., 1992), but it is not always clear how much of the change is attributable to mediation and how much change occurs simply by virtue of practice (Grigorenko and Sternberg, 1998). Importantly, some research shows that dynamic indices augment prediction of posttest performance beyond data derived from pretest performance (Day et al., 1997). However, other studies have not confirmed the independent value of gain indices over traditional measures; results on this aspect of dynamic testing are ambiguous (Grigorenko and Sternberg, 1998). From a long-term perspective, some evidence suggests a relation between ability to benefit from mediation and economic and social independence in adulthood among individuals with low learning potential (Lidz, 1997). However, there have been no demonstrations that dynamic assessment actually changes school or work performance or leads to recommendations that change performance (Grigorenko and Sternberg, 1998). In all, dynamic approaches to assessment represent an ambitious but unproven perspective on human intelligence. Moreover, scientific research and, indeed, the practice of dynamic assessment, have fallen precipitously in the last 15 years, suggesting the approach is in decline, its greatest contributions already made.

Concluding Comments

In an earlier article in this Encyclopedia, it was suggested that "The aforementioned approaches to intellectual assessment have shared and unique strengths. With time, it is reasonable to expect an amalgamation of these strengths such that, with the addition of practical biological measures of intelligence, assessment will become increasingly reliable, valid, fair, and useful" (Atkinson, 2001). In part, this is what has transpired, although the promise of biological measures is over because they do not measure brain–behavior relationships, they neglect the complexity of human behavior, and they do not relate to diagnostic, intervention, or pedagogical strategies. While the dynamic approach to assessment is falling out of the mainstream, its legacy remains in the form of emphases on fair testing and pedagogical relevance. The psychometric and neuropsychological approaches to intelligence testing are in process of merging, based on their joint statistical underpinnings and the flexibility of test construction this permits, increasingly shared paradigms, and amenability to integration through cross-battery assessment. Improved structural models (CHC) will likely result in increasingly accurate measures of *g*, encompassing broader aspects of intelligence. At the same time, greater understanding of CHC and neuropsychological models will move us toward refined assessment of intraindividual differences, with teaching/intervention implications. This integrated approach to intellectual assessment permits successive classification, prediction, and remediation that encompass large groups (e.g., people with average *g*) and the smallest groups (i.e., the individual) alike.

Abstract

Intellectual history as an academic discipline is nowadays taken for granted: learned journals are devoted to it and universities in the UK and the US offer a variety of graduate and postgraduate courses in the field. However, this was not always the case. After a brief panoramic account of its historical development on both sides of the Atlantic, this article will focus on the main work carried out in intellectual history in the last few decades. Particular attention will be given to some practitioners (e.g., Quentin Skinner, John W. Burrow, Stefan Collini) and their methodological approach to the study of past ideas. By concentrating on the practice and role of the intellectual historian, the *object* 'intellectual history' will be presented not only as a vibrant scholarly activity but also as a valuable attempt at understanding our society from a plurality of perspectives. In order not to sound too optimistic about this intellectual enterprise, attention will equally be paid to the *French case* as an instance of a country where intellectual history is still seen with suspicion, and of an academic world where it is not that much studied nor practiced.

Introduction

To be asked 'what do you do for a living?' might be an occasion for displaying one's pride in himself/herself, a way of showing one's ambitions, a source of embarrassment or, less dramatically but perhaps more interestingly, a chance of reflecting seriously on how one spends his/her days. Historians are people who are particularly prone to embark upon this self-examining journey: what instruments do they use when studying the past? What kind of material do they work on? Why do they choose one methodological and/or historiographical approach instead of another?

Intellectual history offers the paradox of a field of research whose practitioners, despite constantly addressing this type of questions, often find themselves under attack for pursuing a historical enterprise which is not, and cannot be, clearly defined; for lacking rigor as well as a recognizable identity; and for being amateurs allergic to archives. A frequently heard refrain has it that, because of its shifty nature, intellectual history is like "nailing jelly to the wall" (Parageau, 2010). In order to tackle these claims, and reveal their manifest narrow-mindedness, this article traces some key historical developments in intellectual history and casts new light on the work of some of its most significant practitioners.

A Historical Take

What is now commonly referred to as 'intellectual history' has a precursor. That precursor took the name of 'the history of ideas' with at its head the American philosopher Arthur O. Lovejoy (1873–1962) – founder of the long-standing *Journal of the History of Ideas* (1940) – who first used the phrase in 1919. Before then, one needs to go back a good couple of centuries and consider the lesson of the German *Aufklärung*, Giambattista Vico's elaboration of his *New Science* (1725) and the Eclecticism of Victor Cousin in nineteenth-century France (Kelley, 2002). Cousin (1792–1867) developed the history of ideas as an independent discipline associated with philosophy, but one where the prevalence was of history rather than of ideas in the Platonic sense. The ideal and the real found thus a bridge, first, in the history of ideas and, subsequently and more cogently, in intellectual history. At the discipline's inception, a crucial discussion saw those who regarded ideas as exclusively the product of the mind ('internalist' perspective) opposed to those for whom ideas had to be placed in their cultural, political, social context ('externalist' perspective). This exemplifies the contrast between the notion of the timelessness of ideas and their transcendent validity, and that of their inescapably historical and contextual nature.

On the basis of this brief – and inevitably selective – account, we can agree with Anthony Grafton that the history of ideas was always practiced, even before becoming part of the discipline of history (Grafton, 2006). In this respect, in the current panorama of higher education the existence of academic chairs as well as of undergraduate and postgraduate courses dedicated to intellectual history, especially in British, North American, and Australian universities, might be taken for granted. Similarly given is that recognition has also been conferred upon it by the foundation of specialized publications such as *History of European Ideas* (1980) and the more recent *Modern Intellectual History* (2004) and *Intellectual History Review* (2007). Intellectual history – we may dare say – has never had it so good. And yet this achievement took a long time to be accomplished and was never short of impasses (Mandelbaum, 1965).

The cornerstone of Lovejoy's work was the investigation of conceptual problems derived from, and intertwined with, history and philosophy. He contested William James' proposition that consciousness and ideas do not have an existence, and argued that there were unit-ideas, which remained constant throughout history but to which varying historical circumstances gave different answers. Unit-ideas framed all great works of literature, art, science, and philosophy in the West (e.g., the great chain of being). They constituted an intellectual continuum recoverable thanks to the critical selection of texts (Lovejoy, 1964). For Lovejoy this did not mean to deal exclusively with the great thinkers, but it entailed to extend

research to popular opinions, so as to grasp problems, questions and experiences of the time under scrutiny (Kelley, 2002).

According to Felix Gilbert, in the late 1930s in the US the term "'intellectual history' had not yet become a household word", even though it had 'gradually' entered scholarly parlance. Gilbert identified Perry Miller's *New England Mind* (1939) as the first work, which could be properly defined as "an 'intellectual history'". One distinct feature of the discipline was its 'search for precision' in reaction to accusations that intellectual historians used words like "'influence' or 'dominating trend'" too loosely. On Gilbert's account, focus on 'exactitude' suggested intellectual historians' willingness 'to compete' with social historians. As a result, intellectual history acknowledged the existence of 'political, economic, and social forces' and underscored its relation to them. For the intellectual historian, this meant to work at the 'crucial point of the historical process' where 'long-range factors', on one side, and 'the individual event', on the other, became connected by 'human consciousness' (Gilbert, 1971).

Turning to Britain in the 1930s, we find another famous historian of ideas, Isaiah Berlin (1909–97), experience a large dose of intellectual loneliness in that "[i]ntellectual history fell between two stools, neglected by philosophy, history and politics alike". In fact, at that time "the study of the history of ideas […] barely existed at Oxford". This is why Berlin accepted more and more invitations to lecture in the US, where "intellectual history, especially of the Russian nineteenth century, had academic standing" (Ignatieff, 1998). On the whole, it is undeniable that in Britain a major contribution to the discipline was given by émigré scholars like Berlin himself and Arnaldo Momigliano (1908–87) – and closer to us by, e.g., Istvan Hont (1947–2013). And this in a climate of open hostility to it shown by other émigré scholars like the *anti-intellectual* Lewis Namier and Geoffrey Elton (Young, 2006).

With the 1950s (notably, in the US) came the rise of intellectual history as a prominent discipline until its phase of 'decline' in the late 1960s, followed by a full-on 'crisis' in the 1970s and early to mid-1980s, when a new style in the 'rethinking' of intellectual history and its identity was fostered by scholars like Hayden White (1928–) and Dominick LaCapra (1939–) (Jacoby, 1992). Writing in 1977, Paul. K. Conkin stated that in the US "[i]ntellectual history now seems as dated as narrow ties", to the extent that only "a peculiarly reckless graduate student" could "don the label and move with it into a perilous job market" dominated by fashions (Conkin, 1977). Ten years later *and* in Britain, John W. Burrow too spoke of the lack of 'recognition' accorded to intellectual history (Cuttica, 2014). So much so that he epigrammatically declared that "the fate of an intellectual historian" was "to feel at best marginal in the company of 'proper' historians and, when giving talks, to be playing what Donald [Winch] calls 'away matches'" (Burrow, 2009). In a similar vein, Stefan Collini has pointed out that while historians of philosophy work on past texts, which have been reputed to be *philosophically interesting*, intellectual historians are condescendingly given the task to deal with the rest, that is with the less interesting philosophical writers or ideas of the past (Collini, 2001).

Significantly though, Burrow's contribution to assessing the status of the discipline written almost 20 years later offered a much more optimistic picture. In fact, he spoke of the 'revolution' that had occurred in 'the academic standing' of intellectual history in England (Burrow, 2006). A key role in this important change has no doubt been played by the Cambridge School (a misnomer) principally identified with John Dunn (1940–), John G.A. Pocock (1924–), and Quentin Skinner (1939–) and by the University of Sussex among whose original members were Burrow himself (1935–2009) and Collini (1947–).

The Cambridge School

The 1960s and, above all, the 1970s saw the emergence of the contextualist approach to the history of ideas pioneered by Dunn, Pocock, and Skinner (scholars engaged in the history of political thought). Shifting the traditional focus from the great authors of the past taken as immortal and coherent voices of eternally valid truths, the history of ideas became the history of languages, discourse, paradigms, vocabularies, ideologies in historical context. Instead of being seen proleptically (as the anticipation of other doctrines in the present) or anachronistically (as the projection in the past of concepts elaborated now), ideas were interpreted by placing the texts in which they were conveyed within their intellectual milieu. Dunn adopted this method to study John Locke (1969), while Skinner set forth this way of reading past authors in articles on Hobbes (1960s) and in *The Foundations of Modern Political Thought* (1978); as for Pocock, one needs to consider his influential *The Machiavellian Moment* (1975). Despite sharing a general methodological take on the past, these scholars hold by no means the same views.

In particular, whereas Pocock studied the theories expounded by thinkers at different times by capturing the various languages they spoke (e.g., the language of the ancient constitution, natural law, classical republicanism, politeness, and civility (Pocock, 1985, 2009)), Skinner concentrated on the intentions of the authors. This means to look at texts as the articulation of stances in a dialogue in which a great role is played both by the exchange of ideas and by the constant invention of arguments and counterarguments in controversies. Endorsing this view enables readers to ask which works and which theorists certain texts responded to and why specific languages were chosen to defend a specific political position. Skinner's reelaboration of the theory of 'speech acts' – formulated by J.L. Austin and John Searle – helps to grasp authors' concepts by paying attention to the multifarious ways in which language(s) and discourse(s) function. Moreover, Skinner stressed the importance of considering the doing(s) when exploring the meaning(s) of texts.

The Cambridge School forcefully criticized Lovejoy's 'unit-ideas' for failing to explain how these were used and interpreted by those who did so in their contexts. Ideas (and concepts) mean something for people and their audiences, and are connected to the authors' goals and vocabularies (synchronic approach). Ideas also change over time and patterns of new meanings intervene in different historical phases (diachronic approach). Most importantly, the linguistic approach to political texts pursued by Pocock and Skinner (influenced by authors like R.G. Collingwood and Ludwig

Wittgenstein) differs from the perspective of Reinhart Koselleck's *Begriffsgeschichte* (whose influences lie with Carl Schmitt, Martin Heidegger, and Hans-Georg Gadamer).

German *Begriffsgeschichte*, Michel Foucault, and French Dismissal

Begriffsgeschichte (the history of concepts or conceptual history) originated in the late 1960s and it is generally associated with Otto Brunner (1898–1982), Werner Conze (1910–86), and, above all, Reinhart Koselleck (1923–2006). Their attempt was to connect concepts with social history, examining structural modifications in politics, economy, society. They paid attention to semantic change ('keywords') within social and political contexts. Their *Geschichtliche Grundbegriffe* (1972–97) placed the language used to discuss the state, society, and economy in relation to the strata, groups, and orders that employed or rejected such a language (Richter, 1987). For Koselleck, the fundamental moment in old-Europe German-speaking history was what he called *Sattelzeit* (1750–1850) that signaled the transformation of concepts used in political and social language. This involved the advent of modernity whose key concepts were identified with 'historicization', 'ideologization', 'democratization', and 'politicization' (Cuttica, 2012).

By focusing more on the practical implications of concepts rather than on their linguisticality, Koselleck's perspective incurred the criticism of the Cambridge School. The divergence between the two methodologies recalls what Pocock defined as the problem of the separation/unity of social structure (manifested, for instance, in official languages) and discourse (intended as speech and intertwined with debate) (Pocock, 1987). As for Skinner, *Begriffsgeschichte* detaches concepts from their specific historical settings. It also undermines the role of human agency in the formulation of opinions and theories. According to Skinner, the problem with *Begriffsgeschichte* is its identifying a text as the byword of a static *mentalité* which, in turn, is the expression of a given social formation (Bevir, 2000). Nonetheless, the two approaches share a vigorous rejection of those historiographical currents, which see ideas as passive utterances of a specific social reality or as eternal essences (Tully, 1988; Skinner, 2002).

If this account shows some differences between conceptual and intellectual history, it is also worth recalling that Michel Foucault (1926–84) – well known for his genealogical method – distinguished the history of thought (implying a process of detachment from one's convictions), the history of ideas (the analysis of systems of representations through which we see the world), and the history of mentalities (the analysis of the type of action and attitudes which give meaning to it). Thought expresses our freedom in relation to what we do, so as to establish this as an object and reflect on it as a problem. Hence Foucault referred to a 'history of problematics'. This approach does not entail deconstruction, but a critical analysis where one tries to see how different solutions to a problem have been constructed, and also how these solutions stem from a specific form of problematization. Foucault analyzed discourse as the totality, which characterizes our horizon in history. In other terms, he argued that there is no unified subject whom we might take as an agent of meaning. Rather, there is a dispersion of the (historical) subject. According to its critics, the history of discourse erases the singularity of the individual and his/her creativity (Rabinow, 1991).

The reference to Foucault serves to introduce the historical neglect of the history of ideas in the French academic world. As François Azouvi piquantly remarked more than 20 years ago, outside France to be an intellectual historian does not make one a source of national disgrace (Azouvi, 1992). A key reason for this situation has to do with the predominance of philosophy not only as an academic discipline but also as a fundamental subject in the French teaching system. The history of philosophy has been regarded as having more 'substance' than the history of ideas, as if the object of study attended to by the former had more dignity than that pursued by the latter. While for the history of mentalities and for social history, the history of ideas is too little anchored in the institutional scaffolding of a society, for the history of science and for the history of philosophy it turns out to be too little abstract. The history of ideas has also been accused of spreading some sort of idolatry of the influence and for being deprived of any normative guidance (Azouvi, 1992).

Undoubtedly, the strong role played by the *Annales* school (1950–80) has prevented the development of research in intellectual history, and in the best of cases has tied it heavily with cultural and social history (Roger Chartier). Perhaps, the tendency on the part of (many) French historians to worship archival work might have had something to do with their ignoring intellectual history. It is also important to point out that in France intellectual history has often been confused with the history of the intellectuals, a tradition which has been particularly strong from the *affaire* Dreyfus (1894–1906) and Julien Benda's *La Trahison des Clercs* (1927) up to the controversies between Camus and Sartre, and then on to Bourdieu and the philosophers of the so-called French Theory such as Althusser, Deleuze, and Derrida (Dosse, 2003). More interest has thus been poured into a sociology of the intellectuals than into genuinely critical studies of past ideas in context. This series of factors is thereby behind the still very uncertain status assigned to intellectual history, and the hostility with which it is frequently portrayed, in France.

This being said, new generations of – bi/multi-lingual – scholars are now engaging with intellectual history in refreshing fashions (Vincent, 2003; Parageau, 2010). As Sandrine Parageau has recently observed, intellectual history is criticized for its 'obsession' with methodological issues. It is accused of being parasitic with regard to traditional history and it is dismissed as "[a] cuckoo in the historical nest". After all, Foucault attacked the history of ideas for being confusing in terms of disciplinary boundaries, for its extensive borrowing from other disciplines, and for its lack of soundness. According to Foucault, it was not a discipline, but "un style d'analyse". In fact, as Parageau maintains, intellectual history moves fruitfully across disciplines in a *transdisciplinary* rather than simply *interdisciplinary* manner: while interdisciplinarity "invites exchange between disciplines", transdisciplinarity "goes further, and trenchantly proceeds to pursue a true break in the global conception of the world and of science". Therefore, for Parageau this "freedom and creativity cannot be practiced but on the fringes

of academia and its organization, that is to say there where it is still possible to get rid of disciplinary habits and dare undertake new approaches of research" (Parageau, 2010).

This view was first taken 50 years ago across the Channel in Brighton.

Sussex, Burrow, and Collini

Almost from its foundation (1961), the University of Sussex developed a congenial environment in which to pursue interdisciplinary research. With 'an independent syllabus', separate 'admissions' and 'examinations papers', intellectual history at Sussex 'was at one time the only undergraduate degree of its kind' in the UK (it was preceded by an MA program). The first lectureship in intellectual history was assigned to Larry Siedentop in 1972 and was taken up by Stefan Collini 2 years later (Collini, 2000). Thanks to courses like 'Concepts, method, and values in the social sciences' (CMV), Sussex benefited from a system of joint teaching involving literature, history, philosophy, and the history of science. The CMV's threefold methodology drew on "the history of ideas or intellectual history", attempting "to establish the filiation of particular ideas or schools of thought, their origins and lines of mutual interaction"; on "the approach of the social historian" investigating "the link between social science and the efforts of particular groups or individuals" to improve society and implement ideals into practice; and on "the social scientists approach to the history of social science" (Cuttica, 2014). Together with Siedentop and Collini, Hellmut O. Pappe, Donald Winch, John W. Burrow, Michael Moran, and others formed 'a group of like-minded scholars' who carried out research and teaching, which refused to embrace academic tribalism and departmental straightjackets. Interestingly, according to Collini, to speak of a 'Sussex School' would be 'a culpable form of exaggeration or reification' in that there never was such a programmatic adherence to one 'explicit and exclusive' method (Collini, 2000). Such an idyllic situation lasted until the axe of the government fell on small departments which were by decree incorporated within larger academic units (Cuttica, 2014).

The best way to sketch the significance of the Sussex experience is by illustrating some of the most original ideas on the *métier d'historien* elucidated by Burrow (who moved to Oxford University in 1995) and Collini (who moved to Cambridge University in 1986). The former was a prolific author of monographs devoted to unravel the complexity of many intellectual aspects of modern European culture. Averse to methodological abstraction, Burrow pursued history knowing that the latter – following Burckhardt's maxim – is "the record of what one age finds of interest in another" (Cuttica, 2014). Elegant, sharp, and erudite, Burrow's writings championed the importance of history as a narrative of the past according to its actors in contrast to readings of it imbued with presentism-tailored goals. With Collini and Winch, Burrow explained that the intellectual historian ought "to be alive to the several dimensions of the thought and feeling of the past". This means to be receptive to 'the sensibilities' of various authors; 'to the emotional and aesthetic satisfaction' past theorists 'derived from their views'; to their 'styles'; to the 'genres' through which they conveyed their principles; and to the tension between their search for 'coherence' and their 'deeply felt intuitions' (Collini et al., 1983).

Burrow viewed the practitioner as an explorer whose adventure consists in a 'genuine negotiation' with past utterances, whereby he/she both listens and speaks to them. To listen to past dialogues is a way of overcoming 'the parochialism of the present' and of enabling one's audience 'to listen with an understanding which is not superficial but intimate'. For Burrow, we need to pursue a 'two-sided' engagement with historical phenomena whereby we retain the ability to be surprised by them and their unexpected tonalities. In an equally intriguing fashion, Burrow portrayed intellectual historians as both eavesdroppers on the conversations that went on in the past and translators (Burrow, 2006). As eavesdroppers, they mingle opacity and clarity. As translators, they do not play the role of sympathetic actors reexperiencing events, but focus on transmission. They are a sort of go-between bringing to life the voices of the past. To study history means to travel back in time (and then forward into the present) equipped with concepts, which are our own and through which we attempt to make *some* sense of what took place before. To do so thoroughly is to rethink the categories we apply in our exploration of past ideas and events. All historical reconstruction has thus to be informed by a certain amount of creativity. From this reconstructive attempt emerges an intellectual historian who 'can be bothered to disturb' the 'oblivion' to which too many opinions – now unfashionable, when not disparaged as absurd – have been, and are, confined. To write intellectual history has nothing to do with what *we* think to be important at a given time, but it concerns what past actors considered relevant *then*. Therefore, its practitioner is more interested in highlighting 'intellectual dead ends', which were once fostering debate, than in concentrating on 'portentous moments, which were then not recognized as such'. To undertake this scholarly route means to descend closer to the pulse(s) of the intellectual life of past epochs (Burrow, 2000).

From nineteenth-century historical studies to analyses of the current state of affairs in our universities, Stefan Collini is an eclectic intellectual historian and a widely read author of critical essays and reviews for a multiple range of English-speaking publications. At home in different genres and styles, as well as in a broad spectrum of chronologically disparate topics, Collini writes about complex themes in a manner which, without losing in depth or elegance, is capable of reaching a public vaster than that usually addressed by the majority of academics. Collini has defined his intellectual trajectory as follows: "My formation is very much that of an historian, trained in England and the United States, working primarily on English intellectual history; after doing some work on the history of political thought and the history of sociology, my interests have moved more towards the history of cultural and literary criticism" (Collini, 1988). For Collini, "labels like 'intellectual history'" are thus no more than 'flags of convenience': they are not 'names of essences'. Hence 'those who apply the label to themselves' do not have 'any monopoly on right-minded historical practice'. Like Burrow, Collini prefers the term "intellectual history" to "the history of ideas" because the former underscores the involvement with a 'human activity' rather than with mere abstractions taken as

independent and a contextual object of study. This is why "the best work in intellectual history precisely attempts to give their proper place to…social forces, institutional frameworks, political pressures" in the life of thought and its agents.

In Collini's view, one central concern for the intellectual historian is the instability of all disciplinary boundaries. Disciplines are complex compounds of different 'practices' assembled as a unity thanks to intellectual coherence just as much as to 'historical accident or institutional convenience'. Their multifarious developments and the ways in which they change are the object of research in intellectual history. Thus, intellectual history-driven questions concentrate on why and how a certain label has been assigned to a certain scholarly activity, and consequently this leads to delineate the ambitions, interests, and convictions prevalent in a given society at a specific historical juncture. Collini calls for historians to emancipate themselves from the strictures informing 'disciplinary history' (Collini, 2001). In fact, whereas "discipline-history bores a 'vertical' hole in the past (with all the consequent dangers of 'tunnel-vision'), intellectual history attempts rather to excavate a 'lateral' site, to explore the presuppositions, ramifications, and resonances of ideas, which may often involve pursuing them into neighboring fields" (Collini, 1988).

Drawing on his critical assessment of C.P. Snow's famous and controversial 1959 Rede Lecture, *The Two Cultures*, Collini invites scholars to confront 'larger questions', which have to do with society, so as to expand a dialogue that is not confined to the frequently navel-gazing specialism of one's own profession. In this respect, he refers to 'brilliant individuals like Stephen Jay Gould, Richard Dawkins, or Stephen Hawking' as men of science *and* authors capable of engaging wide audiences without diminishing the degree of creative thinking and scientific rigor of their work. In so doing, it is possible to communicate clearly with 'a nonspecialist readership' and transmit to it the importance of highly specialized and 'technical research' (Collini, 1998).

Another major feature of Collini's writings is their de-mythologizing a series of *idées recues*, which hinder genuine historical understanding. This practice has been applied to debunk what he has called the 'absence thesis' whereby Britain is traditionally depicted as a land lacking intellectuals or one inhospitable to them compared to other countries. Collini has shown the paradoxical nature of many culturally ingrained claims about an object of study, a fashion, a tendency, or a situation. In this respect, he is a dismantler-cum-flair of all rigid assumption impoverishing the historical perspective (Collini, 2006). Allergic to the blinkered theoretical imperatives imposed on historical research, Collini has made clear that "the merits of the history written depends on qualities which no theory can adequately prescribe" (Collini, 1985). In line with this idea, and thanks to a prose sparkling with piercing irony and impressive learning, his writings embody the vocation to abandon 'the ghetto mentality' stifling academic research and to move away from specialists' entrenched 'disdain for communicating' the results of their work more broadly. Indeed, this openness is part and parcel of the type of intellectual history originally made in Sussex whose brand was the promotion of "a public language in which nonquantifiable considerations can be given their proper weight" (Collini, 1988, 1998). Perhaps, Collini's pursuits help delineate a new identity for the practitioner as critic – literary, political, cultural – whose feet are well-grounded in the sticky fields of historical narrative and whose voice reaches audiences not confined to the usual arenas of intellectual exchange.

Intellectual History and Its Future: The Practitioner

Taking the cue from Lovejoy's dictum that "the history of ideas is no subject of highly departmentalized minds" (Lovejoy, 1964), it would be professionally parochial and scholarly unhelpful to prescribe a series of criteria or, worse, rules enabling to identify *true* intellectual history from fake ones. Perhaps, less arrogantly but more usefully, one could point to some – nonexclusive nor exhaustive – traits that inform the practice of intellectual historians now working on varied topics from a plurality of perspectives. To do so might dispel some of the confusion that often shrouds all attempt at drawing intellectual history's (very mobile) borders. It might also provide an idea of future research directions likely to be taken by a large number of those who to the question opening this article would be *brave enough* to answer 'I do intellectual history'.

- Rigorous analysis of texts and critical examination of their content combined with close attention to the material conditions of their production and literary forms; their cultural and socio-political contexts; and their assumption about, e.g., gender, race, and identity.
- Interdisciplinarity and cross disciplinarity.
- Focus on the linguistic behavior of agents in the past.
- Insistence on the contextual dimension of ideas.
- Analysis of locutionary and illocutionary acts (the doings of the agents when performing linguistically), which involves a good degree of attention to the web of meanings, which gave a particular utterance or text their contemporary significance (importance of historical distance in that one deals with assumptions, opinions, references that are not his/her own).
- Equal relevance to failed ideas just as much as to successful and coherent ones. Intellectual history studies *wrong* principles and does not seek truth in the same way as it is often pursued by philosophers.
- Study of the (long-term) consequences, implications, and legacy of ideas, which, in turn, leads to concentrate on their being distorted, manipulated, or simply adjusted to new epochs and/or cultural milieus.
- Rejection of periodization as a way of fixing the boundaries between, say, 'medieval', 'modern', and 'contemporary', and consequently establishing strict areas of competence-expertise between historians.
- Interplay of diachronic–synchronic approach.
- Criticism of anachronism and prolepsis.
- Writing of intellectual biographies where the life of ideas receives as much heed as the personal sphere of the individual(s) treated.
- Interest in the materiality of things-objects charged with cultural significance (e.g., museums, houses, villas, monuments, scientific instruments, places of science).

- Expansion of the range of sources considered as valuable objects of critical exploration (e.g., poetry, fiction, paintings, nature, photographs).
- New consideration for gender and the role of women as agents of intellectual creation as well as for noncanonical authors or once-marginal topics (rejection of elitism).
- Extension of intellectual history studies to non-European, and non-Western, materials, topics, cultural regions (e.g., recent developments in Middle-Eastern, Chinese, and pre-Columbian civilization studies).

These features are intertwined with what Donald Kelley saw as the opening up of intellectual history to new avenues of research: namely, a move from thought to discourse; from the conscious to the unconscious; from creation to imitation; from intention to meaning; from authorship to readership; from the history of ideas to the social history of ideas; from tradition to canon formation; and from the sociology of knowledge to the anthropology of knowledge (Kelley, 1987). Similarly, David Harlan explained that intellectual history cannot ignore the salient part that 'postmodern literary criticism' plays in the investigation of the past and the questions it raises about the conceptual foundations on which historical work stands (Harlan, 1989). Hence intellectual historians' engagement with the issues of 'representation' and 'narrative'. By and large, these considerations confirm the central position held by language in the field: after all, as Kelley once wittily put it, "[l]anguage is an ocean in which we all swim and where we are fishes and not oceanographers" (Kelley, 2002).

Conclusion

Having delineated (by no means exhaustively) the past, the present and the future of intellectual history through the careers and works of a number of historians, a few final words might be spent in sketching a – modest – picture of the practitioner in the here and now. Opponent of the banal, iconoclast of the simplistic and promoter of the obsolete, the intellectual historian unmasks ideology and refutes the truth of a (pretended) *fact*. As critic, he/she turns into debunker of the accepted, dismantler of clichés, saboteur of the assurances of his/her readers, trespasser of academic nomenclatures. Most importantly, given that – as Brian Young has argued – intellectual history contributed 'to shape' the twentieth century just as it was molded by it, with both positive and tragic consequences, and that intellectual historians underwent on their skin the brutality of actions which derived from the ideas of historical figures as much as of fellow practitioners (Young, 2006), it is all the more decisive to reflect on their role in our contemporary society. In a(n academic) world increasingly dominated by the dictates of managerial leadership and by the disconcerting assertions of market-driven philistinism, the intellectual historian has the urgent task to alert a wide(r) public to how concepts and ideas (e.g., immigration, wealth, education, toleration) are nowadays employed in an uncomprehending and historically distorting manner by those in charge of the common good. As a stylist whose trained imagination has the liberating power of bringing together the familiar and the unfamiliar, the known and the unknown, he/she might begin by rethinking the conditions of knowledge available to twenty-first-century men and women.

Intellectual Property Rights: Ethical Aspects

Joseph Straus, Max Planck Institute for Innovation and Competition, Munich, Germany; and NIPMO-UNISA Chair for Intellectual Property, University of South Africa (UNISA), Pretoria, South Africa

Abstract

This article discusses the main notions and categories of intellectual property. Some of the specific conceptual problems of intellectual property are highlighted, such as that they refer to intangible objects. Intellectual property rights are shown to have deep historical roots (e.g., in questions of book authorship), yet their role has also changed substantially due to scientific, technological, social, economic, and political developments. The article highlights how new questions of protecting genetic information and leaving material (including higher life forms) are blurring the boundaries between nonpatentable discoveries and patentable inventions. Major institutional reforms of intellectual property rights, such as those effected by the Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPS) under the World Trade Organization, are raising new questions about how to deal with intellectual property rights fairly at an international level.

'Intellectual property rights' are generally understood as an instrument of economic policy providing incentives for and rewarding a broad range of useful human creativity. Despite this prevailing economic rationale, the roots of, the justification for, and some limitations of exploitation of these rights are reasoned ethically. They will be examined in the context of the notion, economic importance, and implications deriving from scientific and international policy developments.

The Notion of Intellectual Property Rights

As a generic term, intellectual property rights stand for patents relating to inventions in all fields of human endeavor; copyright covering literary, artistic, and scientific works; neighboring rights dealing with performances of performing artists, phonograms, and broadcasts; trademarks, service marks, and commercial names concerned with signs distinguishing goods and services as well as economic subjects; industrial design protecting novel and original ornamental or aesthetic aspects of a useful article; or plant breeders' rights relating to new varieties of plants. Conceptually, intellectual property rights can be understood as rule-governed privileges that regulate the ownership and exploitation of objects which are to be characterized as intangible or incorporeal, thus abstract or intellectual. These objects are nonexclusive, since they can be in many places at once, and can be used at the same time without being consumed by their use. The possession or use of such an object by one person thus does not preclude others from possessing or using it as well. Despite their common fundamental character, i.e., being rights in intangible, abstract objects, and being territorially limited, they differ from each other in many legal details and character.

Whereas a patent also gives its owner rights against the independent creator of a similar invention, copyright confers rights against copying but does not affect the independent creation of a similar work. In other words, while patents restrict the actual usage of an idea, copyrights restrict only the copying of an expression of an idea. Necessarily, the period of protection, i.e., during which the rightful owner can prohibit unauthorized use, is tailored according to the specification of the respective rights – for instance, 20 years from filing the application in case of patents, 50 or 70 years after the death of the author in case of copyright, or renewable at will, i.e., indefinite, in case of trademarks. However, neither patents, nor any other intellectual property rights, confer on their owner a license to use the patented invention, copyrighted work, etc. Such use is prohibited whenever it would violate, for instance, laws dealing with public health, safety, environmental protection or certain ethical standards, or would infringe the rights of third parties.

Economic Importance

Due to enormous advances in science and technology, in particular in communication and information technologies, biotechnology, and life sciences in general, on the one hand, and the global economic policy developments following the conclusion of the GATT-Uruguay Round and the establishment of the World Trade Organization in 1994, on the other, intellectual property rights have gained the most remarkable economic importance. They have penetrated, or are about to penetrate, new areas of economy, such as the service sector, life sciences, and agriculture. Patents have been granted for instance, for microorganisms, plants and animals, genes, as well as computer programs, and business methods. Universities and other academic institutions, primarily aimed at generating and disseminating new knowledge, have also not remained unaffected. Consequently, the new, knowledge-based economy has been characterized as 'intellectual property economy' or 'intellectual capitalism.' This trend is reflected, for instance, by the number of patent applications filed worldwide, which doubled from approximately 1.05 million applications in 1995 to around 2.35 million applications filed by 2012 (WIPO IP Facts and Figure 2013); by the amount of royalties paid for patent licenses, which increased in the USA from US$3 billion in 1980 to over US$100 billion in 1997 (Rivette and Kline, 2000); or by the fact that the ratio of intellectual capital to total market capitalization of US companies grew

from about 17% of company value in 1975 to 80% in 2005 (Blaxill and Eckardt, 2009). Also remarkable are the numbers of US patents issued to US universities, which went up from 177 in 1974 to 5145 in 2012, the year in which US universities filed some 14 224 new patent applications and had an income of US$1.9 billion from running royalties (Straus, 2008; AUTM, 2013).

Historic Roots and Rationale

The historic roots of patents and copyrights, as the two forms of intellectual property with the longest tradition, go back to the systems of inventors' and printers' privileges at the close of the Middle Ages. Inventors' privileges formed part of the industrial policy of regional sovereigns, being aimed at promoting domestic crafts and industry, and at transferring to their own country the production of goods which had previously been imported from abroad; thus, as expressed in a grant issued by Edward III in 1331, *instruendi et informandi causa*, i.e., for the purpose of instructing and informing. The first statutory regulation, the Venetian Statute of Inventors, of 1474, with its time-limited protection of inventions against imitation, was also intended to stimulate 'deep thinkers and ingenious inventors from other regions to exercise their activity to the advantage of Venice.' Similar economic rationale is to be observed in the English Statute of Monopolies of 1624, under which the grant of patent monopolies of 14 years' duration was restricted to the 'real and first inventor,' and was conditional upon its not being contrary to law or 'mischievous to the state' in any way.

Following the invention of the press, the first printers' privileges were granted in the second half of the fifteenth century in Venice, later followed by Milan, and at the beginning of the sixteenth century by other Italian cities, France, Germany, and England. Whereas in Venice and France, some of these privileges were granted to authors, the great majority of privileges were for publishers, or, as in England, for stationers, who acquired a work from its author and organized its printing and sale. In England, where the stationers in 1534, gained protection secured by the Crown against the importation of foreign books, and in 1556, a Charter from Queen Mary, the privileges were combined with censorship over all publications, by mandatory registration with the Stationers' Company. Although the first Copyright Act, issued in 1710, in the reign of Queen Anne (the Statute of Anne), conferred the 'sole right and liberty for printing books' for 14 years to authors and their assigns, it did not change fundamentally the economic rationale of protection.

By naming booksellers and printers as falling among the author's assigns, it demonstrated that the right "stemmed from commercial exploitation rather than literary creation pure and simple" (Cornish and Llewelyn, 2003). Despite the remarkable influence which John Locke's theory – that all persons have a natural right to hold property, particularly the fruits of their own labor – played from the very beginning in justifying intellectual property, the economic policy of legislation has remained utilitarian. This is well demonstrated by Art. 1, Section 8 of the US Constitution of 1787, providing that "The Congress shall have power … (8) To promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries." This is equally true for the first modern patent laws which were passed in 1790 in the US and 1791 in France, although they strengthened the position of the inventor and awarded him a property right to his ideas. The same rationale controlled also the first US Copyright Statute of 1790.

The doctrine of intellectual property developed in eighteenth-century France, advocated primarily by D'Héricourt, Diderot, and Voltaire as a weapon against extended privileges of publishers. A first true statutory shift of the emphasis from the publisher to the author can be observed in the Decrees of the French revolutionary legislation of 1791 and 1793, which extended the term of protection to the entire life of the author and beyond; first for 5, then for 10 years after the author's death. In the course of the nineteenth century, France further extended the term of protection to cover also the life span of the author's widow, and 20 (later increased to 30) years for the benefit of the children. Eventually, in 1866, the duration of French copyright was extended generally to 50 years after the author's death. Even this shift of emphasis, however, did not add to the economic rights of the author any 'personality right' or *droit moral*, which had been first mentioned by Immanuel Kant. Kant stated that the right of the author "is not a right in an object (*in re*), i.e., in the copy (for the owner can burn this up before the author's eyes), but an innate right, inherent in his own person, which implies the possibility of opposing the attempt of another person to compel him to speak against his will." Kant characterized copyright as a supremely personal right (*jus personalissimum*) (Strömholm, 1983).

French and German legal doctrine and French case law in the second half of the nineteenth century eventually paved the way for *droit moral*: first, into the case law, and then into copyright statutes of the principal Continental countries. Although *droit moral* was introduced into the Berne Convention for the Protection of Literary and Artistic Works of 1886, as revised in 1928, in Rome, with a new Article 6 bis – which at present guarantees an author independent economic rights, and even after their assignment, "during his whole lifetime the right to claim authorship of the work and to object to any distortion, mutilation or other alterations thereof, or any other action in relation to the said work, which would be prejudicial to his honour or reputation" – the common law countries of the UK and the USA remained reserved in this respect. In general, therefore, one distinguishes between 'author's rights' of civil law countries, with their emphasis on the principles of natural rights, and the 'copyright,' rooted in the idea of utilitarianism, of common law countries. However, on balance, it was neither human rights nor copyright doctrine that decisively shaped the law, but economic interests of copyright owners, because: "In the world of copyright policymaking, a Canadian book publisher has far more in common with a Japanese book publisher than it does with a Canadian librarian who wants to make free copies for library patrons" (Goldstein, 2001).

International Legal Developments

The very nature of the objects to which intellectual property rights relate, and the development of international trade combined with the progress of transportation and

communication technologies, already by the nineteenth century revealed the need for international instruments for protecting intellectual property rights. What started in 1883, with the adoption of the Paris Convention for the Protection of Industrial Property, followed by the Berne Convention for the Protection of Literary and Artistic Works in 1886, – which established the principles of national treatment or nondiscrimination and minimum rights as binding standards for the contracting states – subsequently developed into a true network of international conventions and treaties covering the entire range of intellectual property rights under the administration of the World Intellectual Property Organization (WIPO).

However, membership in many important conventions long remained limited, and minimum rights incomplete or, as in the case of patents, nearly nonexistent. The turning point came when, during the GATT-Uruguay Round negotiations, issues of international trade, including membership in the World Trade Organization (WTO), were linked directly to an effective protection of intellectual property rights, and the International Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPS) was adopted in 1994. Under this new umbrella for international protection of intellectual property rights, all members of WTO accepted unified high standards of protection, including protection requirements, content, and limitations and duration of rights as well as their enforcement. Developing countries, countries in transition, and the least-developed countries were granted transition periods.

Old and New Ethical Aspects in Intellectual Property Rights

Traditionally, ethical aspects in intellectual property rights have been discussed in the broad context of justification of these rights. Lockean theory of natural rights to the fruits of one's labor, the doctrine of intellectual property, as well as Hegel's personality justification suggesting that the best way of progressing science and the arts is to protect scientists and artists from theft, so as to become the basis for learning by others, are such examples, and had some lasting influence on legal developments, reflected, inter alia, in broad acceptance of *droit moral*. Modern critics of intellectual property rights also put emphasis on ethical aspects when, for instance, claiming that increasing scope of patentable subject matter or legislatively creating new forms of abstract objects, such as plant variety rights, constitutes effectively the creation of capital, which has the danger that it can act as an enormous power resource for a select few. Furthermore, a global protectionist scheme for intellectual property would help to promote the formation of global factions, resulting in the danger of global rent seeking, and perhaps providing temptation to multinational elites to increase their profits through the simple stratagem of persuading a supranational body to elevate levels of protection for abstract objects already in existence (Drahos, 1996). With such reasoning, neither the ethics of the controlling doctrine nor the ethical aspect of attempts to take care of the developing world and the unprivileged in general can be overlooked. The same is true for the debate on intellectual property rights in genetic resources and benefit sharing. Although clear empirical evidence whether intellectual property rights confer a net benefit or a net loss upon society is still missing, modern lawmakers seemingly accept a limited and flexible intellectual property rights scheme as a reasonable and, as revealed by the adoption of TRIPS, internationally necessary effort to maximize benefits while minimizing costs. This attitude is demonstrated by the adoption of statutory rules or acceptance of case law, creating new objects such as DNA sequences, monoclonal antibodies, or for instance, business methods as subject matter of protection. In their overall positive attitude toward exclusive intellectual property rights modern lawmakers might have been in part influenced by the negative experience with some alternative protection found in the former socialist states such as 'investors' certificate' which did not provide for exclusivity and had no beneficial macroeconomic effects.

Special attention is paid to ethical aspects when patentability of inventions is at hand, the commercial exploitation of which would be contrary to '*ordre public*' or 'morality.' Under the TRIPS standards, members of the WTO "may exclude from patentability inventions, the prevention within their territory of the commercial exploitation of which is necessary to protect *ordre public* or *morality*, including to protect human, animal or plant life or health or to avoid serious prejudice to the environment, provided that such exclusion is not made merely because the exploitation is prohibited by their law." Thus such exclusions may only apply for ethical reasons, first, if commercial exploitation is prohibited, and, second, if they are prohibited for specifically qualified reasons, which need not necessarily be set out in statutes, however. European patent law reflects these ethical considerations by excluding from patentability the human body, at various stages of its formation and development, including germ cells, processes for cloning human beings, processes for modifying the germ line genetic identity of human beings, uses of human embryos for industrial or commercial purposes, processes for modifying the genetic identity of animals, which are likely to cause them suffering without any substantial benefit to man or animal, and in general all therapeutic methods. By declaring, explicitly in principle, that biological material, even that of human origin (provided the prior informed consent of the source person is obtained), as well as animals and plants (except varieties) is patentable, European lawmakers demonstrated clearly that they do not share respective ethical objections against patentability of life forms. This ethically reasoned approach, which differs in particular from that applied in the USA, where no such exclusions exist, however itself raises ethical concerns. On the one hand, it seems consistent that inventions, which for reasons of ethics may not be commercialized, should also not be patented, although an issue of a patent does not confirm more than that the usual patentability requirements of novelty, inventiveness (nonobviousness), and industrial applicability (utility) were met and the invention adequately disclosed. It does not contain any other value judgment. On the other hand, the invention under such circumstances cannot be commercialized in any case, as long as its exploitation is prohibited. However, if such a ban were to be lifted, anybody could use the invention, and the inventor would remain empty-handed. As history demonstrates – for instance, with contraceptives – this is not a far-fetched scenario and could easily happen again,

e.g., with regard to specific uses of stem cell technology, germ line gene therapy, etc. Empty-handed inventors, and at least to the same extent the lack of incentives for investment in potentially useful research, may be viewed as ethically doubtful results.

It should be noted, however, that under the case law of the Court of Justice of the European Union (Judgment of 18 October 2011 in Oliver Bruestle v. Greenpeace e.V.), inventions related to human embryonic pluripotent stem cells, generated from destroyed human embryos are excluded from patent protection under the aspect of ethics. This is true even though the actual working of the claimed invention does not require any further use of human embryos and the generation of stem cell lines from human embryos was fully in compliance with the applicable law. Also, the fact that products generated from human embryonic pluripotent stem cells can be commercialized in a number of EU Member States, does not matter. This raises not only questions of TRIPS compliance of the respective case law, but also of ethics in view of the fact that without patent protection free copying is allowed. Finally, mention should also be made of the case law of the US Supreme Court (Opinion of 13 June 2013 in Association for Molecular Pathology et al. v. Myriad Genetics, Inc. et al.), under which genomic DNA sequences are declared non-patentable as a naturally occurring product, even as isolated DNA segments. This indirectly reflects the ethical consideration that discoveries cannot be treated as patentable subject matter.

Intellectual Property: Law in Context

Christoph B Graber and Jessica C Lai, University of Lucerne, Lucerne, Switzerland

Abstract

Intellectual property (IP) law is often viewed as static, when it is actually chameleonlike, constantly changing to reflect technological and social developments. This article discusses how IP as we know it today – in the classical fields of copyright, patent and trademarks, and in their interaction and beyond – has developed alongside changes in technology, globalization, and society, taking into account their interrelated nature and how they spur propertization and affect the balancing of interests (both economic and noneconomic). It specifically looks at challenges relating to software and the Internet, biotechnology, and overlaps in IP, before taking a brief look at what the future may bring.

Introduction: IP Law as Contingent on the Technosocial

Analyzing intellectual property (IP) law in context invites one to view IP as a protean concept. IP is thus perceived as a set of rules that societies have been developing to regulate access to cultural and intellectual knowledge that is contingent on social and technological development. We should bear in mind that IP rights are an invention of modern society; traditional and particularly indigenous societies have developed different instruments of regulation that are often more concerned with the restriction, rather than the transfer, of rights in cultural heritage assets. Indigenous societies do not conceive of their cultural heritage in terms of exclusive rights but rather in terms of shared responsibilities, as assets to look after for future generations. Generally, they find the commodification of secret and sacred ritual objects and practices to be deeply offensive (Graber, 2009).

The technosocial contingency is obvious in the history of copyright law. There was no need for copyright law or the recognition of 'authors' before technologies were available that made the mechanical reproduction of creative artifacts possible at relatively low cost (Cornish, 2009). It was only the development of tangible commercial value in the form of a book that generated the need to identify its source (Anderson, 2009). The *Statute of Anne* (1709) was the first copyright statute to provide for an individual right to print. Before that the English Crown regulated access to printed information by bestowing selective royal grants of privileges on those craft guilds that respected the Crown's censorship standards (Drahos, 1996).

The development of modern patent law is inextricably entwined with the paradigm of industrial manufacture (Pottage and Sherman, 2010). Although statutory patents have been around since the fifteenth century, the patent rocket only started to take off at the end of the eighteenth century as a response to the industrial revolution (MacLeod, 1988; Pottage and Sherman, 2010), and started to soar in the twentieth and twenty-first centuries with the advent of mass chemical and pharmaceutical production, followed by information technology and biotechnology.

Similarly, the evolution of trademark (TM) law is a response to the development of marketing strategies, communication technologies, and mass media, which created the need to regulate the commercial use of signs (in a very broad sense, nowadays also including colors, sounds, gestures, shapes, and even smells) through a set of specific access rules. As with patents, the demand for protection of marks increased during the industrial revolution and the rise in factory production and greater transport of products. This demand increased again in the twentieth century with the growth of the popular press as a medium for advertising and with the increased ability to transport goods, intensifying competition. More recently, TM protection has swelled with the advent of globalization and technological developments, enhancing large-scale marketing efforts (Cornish et al., 2010).

Theoretical Approaches to IP Law

IP rights are rights in abstract objects (Drahos, 1996); they are rights in *corpora mystica* rather than rights in *corpora mechanica* (material objects). The question that modern society had to answer is why the law of the state should vest exclusive rights in abstract objects. Most influential has been the answer derived from a 'productive misunderstanding' of John Locke's natural law theory of property. At the end of the seventeenth century, Locke argued that "every Man has a Property in his own Person" (Locke, 1994). Therefore, according to Locke, it follows that every man also has property in his labor. Consequently, everything that the individual mixes his labor with is removed from the state of nature and becomes the individual's property (Locke, 1994). Although Locke was writing about material objects and deliberately did not extend his theory to support a perpetual right of authors, through adaptation by William Blackstone in the eighteenth century, this chain of reasoning became the philosophical justification also for property in abstract objects (Deazley, 2004).

Although Adam Smith had written about the effects of regulation on the economy as early as the eighteenth century, it was only in the 1960s that, predominantly in the United States, law and economics set out to establish itself as a new subdiscipline of legal theory (Menell, 2000). Under the growing influence of economic rationality in most areas of law and policymaking, a market-oriented foundation of IP rights gained ground as an alternative to an individualistic (natural rights-based) IP theory. From the perspective of political economy, IP

rights are monopolies vested by the law of the state in right holders to exclusively exploit the right for a certain (in the case of TMs, unlimited) time period. According to a utilitarian rationality, such monopolies are justified because they are deemed necessary incentives for creative people to invest time and money in their creations and share them with other people. Law and economics theories today strongly dominate discourse about IP law, especially as a theoretical foundation of the intersection of competition law and policy. Although some of this scholarship is very sophisticated and well aware that IP law tends to favor private over public interests, it is not able to integrate societal values – like culture, health, privacy, and so on – that compete with economic values and interests. Hence, an economic approach is capable of warding off critique that a given IP system fails to maximize utility for society, but only so long as the critique stays within the internal standpoint of classical economic rationality. Approaching utilitarianism from a moral or ethical perspective may have promise (Singer, 2011; Pogge, 2010); however, this has yet to filter into general IP theory.

Although there is a need for theoretical approaches to IP that are able to embrace noneconomic societal rationales, scholarship that is not confined to economic thinking or to an individualistic natural rights theory is scarce – particularly in the Anglo–American academic world. Influenced by legal applications of sociological system theory, however, new scholarship is emerging that views economic values of IP in a quasiconstitutional relationship with other fundamental values of society (see below, Section Constitutionalization of the Global IP Regime).

Propertization

Societies that justify IP rights with a (pseudo) Lockean theory of labor and natural right tend to overly propertize intellectual and cultural assets to the detriment of the commons (Drahos, 1996). In recent years, we have faced a paradigm shift from a presumption that 'government-granted IP rights are an exception from the general rule of free competition' to a new presumption that every new technological or cultural creation should be legally protected (Merges, 1995). This shift is evidenced by the increasing number of international agreements pertaining to IP, by the higher standards of protection advanced within the World Intellectual Property Organization (WIPO), and, most pertinently, by the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) of the World Trade Organization (WTO). With its broad membership, and by virtue of being binding and strongly enforceable through the WTO dispute resolution system, TRIPS has resulted in the propertization of intellectual assets in states that previously did not have similar IP systems and has allowed established IP states to extend the reach of their property arms into these states.

More specifically with regard to copyright, what constitutes a 'work' has extended beyond traditional literary and artistic works to include, for example, software, fictional characters, and television formats. Rights are broader, encompassing more than the rights to reproduction, communication to the public, translation and adaptation, expanding to distribution, and rental rights. Finally, although international law only requires that works be protected for the life of the author plus 50 years, many jurisdictions (such as the United States, the European Union, and Australia) have extended this posthumous protection to 70 years. Whether permitted uses of third parties (such as for teaching purposes or academic research) have concurrently been widening is contentious, raising issues of the ultimate balance between promoting creativity and allowing for future expression.

Since the early patent laws, the term of patent protection has risen from 14 to 20 years and the scope of the patentable 'invention' has grown to controversial proportions. For example, before the mid-twentieth century, it was not possible to patent chemical products per se in many states. These days, one does not blink an eye at the prospect. The development of new technologies, such as software and biotechnology, are the locus of contemporary controversies in patent law. The seeking of patents by universities and publicly funded research institutes has also become common since the World War II, whereas it had previously been viewed as contrary to the academic environment of such institutions.

Propertization in TM law is reflected in a conceptual shift from preventing fraud or consumer deception to protecting the property in signs used in trade (Bently, 2008; Lunney, 1999; Lemley, 1999). TMs originated from the courts within tort law as an unfair competition tool to prevent a trader from selling goods represented as those of another trader (Landes and Posner, 2003; Bently, 2008). The solidification of TMs as 'property' occurred in the mid-late nineteenth century (Bently, 2008). Although TMs continue to serve to minimize consumer confusion and search costs, and implicitly to indicate certain qualities of the goods on which they are used, these days, the expanding tendencies of TM protection means that, in some cases, reputation and goodwill of marks are protected even when there is no consumer confusion (Landes and Posner, 2003), controversially creating property more akin to copyright and patents (Pulos, 2005–2006). For example, the Paris Convention (Article 6bis) and TRIPS Agreement (Article 16.2–3) together require the protection of 'well-known' marks for goods and services, essentially protecting reputation/goodwill against 'dilution,' or the blurring or tarnishing of the repute of a well-known mark. This reasoning steps away from market concerns, toward protecting TMs as a thing capable of being damaged.

New drivers of propertization are complex things (more fundamental or informational) that could be perceived as being 'technologically normative,' thus adding a layer to the law's normativity. For example, patents can be obtained for genetic code, proteins (complex chemical compounds), or self-terminating seeds, which themselves produce 'technologically normative' effects irrespective of legal regulation. Genes define what chemical/biological structures a specimen can make. Proteins are catalysts that control the reactions of other simpler chemical compounds, determining the end product of a reaction. Finally, crops from self-terminating seeds can only be harvested once, the new seeds being sterile. Copyright protects Internet/software code, which inherently directs the flow of information and what can be done with content on the Internet and with hardware (Graber, 2012a). Furthermore, many copyright laws penalize the circumvention of technical

measures protecting copyrighted works that themselves decide how a work can be used irrespective of existing fair use rights. TM law broadening to protect three-dimensional shapes, possibly the shape of goods per se, has created problems when the shape is functional. These examples have attracted controversy because owners can be seen as being endowed with a combination of legal and technological normativity.

Balance

Balancing exclusive interests of individual right holders against inclusive interests of the general public has always been an important aim of IP law. In theory, a balance within IP law secures that the public benefits overall. In practice, however, the protection of IP rights has the effect of maximizing returns of private right holders at the expense of interests of the public at large. Technological development of the recent past as well as propertization has led to a considerable inflation of the private benefits that can be gained from IP monopolies to the detriment of public interests.

One of the core underlying principles of copyright law is that it protects expressions and not ideas. The ideas/expressions dichotomy is pivotal to the balance between stimulating expression and allowing for users to build off existing works, as ideas are considered to be part of the raw resources of the public, usable for further creativity. This is in part why copyright law is generally considered to be compliant with the constitutional right to freedom of expression and information, because the dichotomy acts as an internal check for the freedom (the 'internalization theory') through limiting use of only exact expression and not of ideas held within works (Torremans, 2004; Barendt, 2005). The idea/expression dichotomy is often painted as black and white, but is actually not as well-delineated as inferred by the internalization theory (Cohen, 2012) and is not on its own capable of protecting freedom of expression (Oliver, 2000; Barendt, 2005). As an illustration, the dichotomy may have little relevance in a networked environment. Take, for example, mash-ups. Users are free to use the ideas behind media works, but actually it is the snippets of expressions that they need to use in order to enjoy their freedom of expression. In fact, the ideas in the original work may be completely irrelevant to their purposes. Thus, although the internalization theory is generally questionable, it is clearly incorrect when it comes to copyright protection on the Internet.

As patent law is based on the premise that it incentivizes invention/innovation, it must be designed so as not to impinge too greatly on future invention. The incentive must be great enough to stimulate invention/innovation, but not so great as to prevent other inventors from creating based on existing inventions. As part of this balance, inventions must be novel, nonobvious (with an inventive step), and have utility (industrial application). It has also long been established that laws of nature, natural phenomena, abstract ideas, and mere discoveries are not 'inventions,' because they make up the basic tools of scientific and technological work that should be available for all to build upon, such that to grant patents over them would impede invention rather than promote it. The development of new technologies such as software, Internet business methods, as well as gene- and life-related technologies has challenged the notion of the discovery/invention dichotomy, because they are closer to (if not actually) natural phenomena or abstract ideas compared to classical inventions, such as purely mechanical machines or methods of producing chemicals or admixtures.

TMs protect balance through only protecting marks capable of distinguishing a trader's goods/services from another's, or marks that have gained such distinctiveness in the market, thus theoretically leaving the generic free in the commons. TM laws further seek balance through only protecting owners from third-party 'use in the course of trade,' which usually means that the mark is used in a TM sense to distinguish goods/services. In theory, these limitations function to respect freedom of expression and the requirement of 'use in the course of trade' particularly to restrict TM owner's rights to those required to prevent unfair competition (Helfer and Austin, 2011). For example, with a book criticizing McDonald's, the TM golden arches should be allowed to be shown on the cover, as not being 'use in the course of trade.' As with patent and copyright laws, TM law also faces challenges with the development of information technology. TMs may be needed to perform Internet searches, for example. Arguably, marks that may be distinctive in the real world may have more of a generic (or at least different) function when only used within code, not even visible to users. The nature of the technology makes it difficult to say what exactly 'use in the course of trade' means within the online environment.

Globalization

The Problem of Territoriality

Despite the increasing number of international and regional agreements, IP law is inherently territorial. The question then is how state-centered legal orders of IP are able to cope with the challenges of economic globalization. Copyright law is particularly challenged by the digital revolution and the Internet, and a territory-based legal structure is difficult to reconcile with consumers expecting easy access to digital content at all times, anywhere and through a multitude of devices. However, ambitions to get rid of copyright territoriality for the sake of creating larger content markets may easily clash with cultural policy objectives. The European Commission's effort to create a single market for copyright-protected products is a case in point uncovering collisions between economic interests of the European Union and cultural interests of member states. The Commission's conviction that Collective Management Organizations should compete in an EU-wide market for the administration of copyrights has been criticized as being one-sidedly economy oriented and ignoring important aspects of cultural diversity (Graber, 2012b).

Territorial thinking in patent law is a legacy of a time when it was difficult and sometimes even dangerous to bring an invention into a country. The trials undertaken to import an invention meant that the initial focus was on the societal benefits of the invention itself (i.e., the physical entity). With globalization and the ease with which we now move the physical, the focus has shifted to the contribution of the information behind the invention (Chisum et al., 2001), and

patent systems encourage inventors to publish the information behind their inventions that they might otherwise keep as trade secrets (Landes and Posner, 2003). That several states continue to have territorial novelty standards (as opposed to absolute standards) reflects a continuance of territorial thinking despite globalization and the shifted focus, and also despite technological developments in communication.

TM law is arguably the most territorial form of IP. This is because whether a mark is distinctive completely depends on the national market. New technologies of transport and communication and globalized business strategies challenge territoriality in TM law. What may be distinctive in one state may be generic in another in juxtaposition to the international nature of modern business. Territoriality is also highlighted by the protection of geographical indications (GIs) (e.g., Champagne) through TM-like regimes. Tension has arisen between 'old world' Europe (along with some other countries, such as India, Thailand, and Turkey) wishing to protect 'traditional' names and associated values even when there is no consumer confusion and 'new world' Americas and other settler states (such as Australia and New Zealand), which view GIs as protectionism, since they tend to be made up of multiple cultures wherein many names/symbols have become generic and are used in a descriptive manner.

There are examples of a movement away from territoriality, such as the development of the European Patent Convention and Community Patent and WIPO's global design registry.

Constitutionalization of the Global IP Regime

Recent scholarship has shown that the fragmentation of international law (UN, 2006) spurred the establishment of a global IP regime (Graber, 2014). This regime is partly formally institutionalized within WIPO, the WTO/TRIPS Agreement, and a plethora of free trade agreements (with IP chapters) and partly institutionalized outside a formal legal setting and without the involvement of states or intergovernmental organizations. Indeed, important drivers of the global IP regime are big transnational corporations of the entertainment and pharmaceutical industries in particular, whose activities may have regulatory effects and produce transnational regime law. Under the disproportionate influence of these powerful private actors, the global IP regime is developing regulatory mechanisms that are, to a certain extent, competing with the public interests of states. Within a theoretical framework that has become known as 'societal constitutionalism' (Teubner, 2012), Gunther Teubner and others have pointed out that world society is shifting from territorial differentiation to functional societal differentiation. Accordingly, the close structural coupling between state politics and the law that determines national constitutionalism does not exist at the transnational and global level, and regimes autonomously develop constitutive and limitative constitutional functions. With regard to the global IP regime, an analysis of societal constitutionalism shows that so far mainly constitutive functions have been developed and limitative elements are almost entirely missing (Graber, 2014). Public discontent with a 'neoliberal' spin on IP law and policy that is held responsible for this one-sided constitutionalization has recently become stronger and activism in social networks has been successful in mobilizing masses against projects of legislation destined to make IP enforcement more effective at the national and global level.

Specific Challenges

Software and the Internet

The question about the adequate legal protection of computer software arose only after IBM had taken the momentous decision in 1969 to unbundle software from hardware and to trade it as a separately priced asset (Bing, 2009). When the United States extended copyright protection to computer software in the 1980 amendment to the 1976 Copyright Act, this had a signaling effect on many other states to follow suit. Since the 1990s, TRIPS and the WCT have required contracting states to protect computer programs as literary works within the meaning of the Berne Convention for the Protection of Literary and Artistic Works. Scholars have criticized the copyright approach to software as mismatched and the analogy between programming language and literary language as farfetched. Whereas literary language may become the medium of a literary work due to its malleability, programming language's 'semantic' is structured as a linear relationship between orders and actions that leave no room for choice or creativity. Similarly, friction arises when distinguishing the (protected) expression in a computer program from the (unprotected) ideas and principles underlying them. Although courts in the European Union and the United States converge in the view that functional behavior of computer programs, programming language, and data formats affecting interoperability are treated as unprotected ideas and principles (Samuelson, 2012), the question whether application programming interfaces should be covered by copyright is currently a much disputed issue with far-reaching consequences for innovation in software.

Many states do not allow patents for software per se, as they are considered to be mere 'printed sheets,' instructions, or mathematical algorithms. However, software can usually be part of an invention. The exact nature of the interaction between software and hardware and whether the end result need be a 'technical effect' or can be merely informational is unclear and from the uncertainty one could say impossible to define. The United States Patent and Trademark Office has taken a very broad approach to what qualifies as an 'invention,' allowing patents that only claim steps for executing software on any computer platform and create informational results, but the courts have been inconsistent in upholding the validity of such patents. What will be accepted by the European Patent Office (EPO) is also nebulous, although it generally requires that a program directly affects the operation of hardware and results in a technical effect (Cornish et al., 2010).

In the late 1990s, 'cybersquatting' TM cases started to appear in the courts, regarding the practice of registering a well-known company domain name and trying to sell it back to the company. Courts were faced with the difficulty of finding 'use in the course of trade,' as the squatters did not actually use the webpages. The term was stretched to fit the new behavior. Concerns have also arisen with 'keyword advertising,' which is online advertising that appears as a result of keywords being entered into an Internet platform (Greene, 2009). Advertisers

buy keywords, often TMs, from the platforms so that their advertisements appear when those keywords are keyed in. For example, a computer retailer, service provider, or tech reviewer may wish to purchase the keywords 'Apple.' Indeed, Apple would also wish to purchase 'Apple,' as would perhaps its competitors. Complicated questions arise on whether there is 'use in the course of trade' (as per registered TM law), misrepresentation and associated loss or damage (for passing off), or consumer confusion (usually required to rely on consumer protection law), and the appropriateness of these terms in the Internet context.

Biotechnology

Biotech patents draw debate for several reasons. The first is that on moral or ethical grounds many do not agree with patenting life forms and gene-related technologies. The second pertains to the fact that such patents more directly affect the way that doctors treat their patients. In comparison to pharmaceuticals, which practitioners do not generally have the means to produce, many laboratories, hospitals, and academic medical centers are capable of making or using patented biotech inventions themselves (Eisenberg, 2002).

Third, biotech patents are often challenged as to whether they are 'inventions,' given their relative closeness to products of nature. What exactly constitutes a natural product or mere discovery, as opposed to an 'invention' is an open and difficult question, as all inventions in some way use and reflect natural phenomena or abstract ideas. In some situations, such as with new minerals, elements, or species found in nature, it is clear that there are only mere discoveries. The status of something found in nature, but extracted from its natural environment, is more difficult, for example, a chemical molecule extracted from a plant, wherein it is normally in a mixture with other molecules, or a genetic sequence extracted from a chromosome. Notably, both the EPO (EPO Guidelines, parts G.II.3.1 and G.III.4) and the US Supreme Court (*Association for Molecular Pathology v. Myriad Genetics, Inc.*, 2013) hold that simply isolated genes or genetic sequences are mere discoveries or natural products.

Finally, biotech patents are seen as too greatly hindering future invention, as they are often informational and fundamental in character. The shift in focus to the information behind an invention (as opposed to the physical invention itself) is problematic as it means that public access to the invention is not guaranteed. Historically, patents could often be struck from the register for nonuse; however, this is no longer the case in many jurisdictions. Patent owners are thus able to seek rent from their patents, although they themselves do not otherwise use them. This is particularly the case for more informational/fundamental inventions, which raises particular concerns because patents have in part been justified based on the costs of bringing a product to market.

Relatedly, there are serious questions about whether the incentive theory applies to all research in the biotech field, given its often fundamental nature. Yet, not all biotech inventions are fundamental and some may be costly to bring to market. Patent law need only incentivize that which would not take place free of its existence. Ultimately, we must ask at what point we should propertize in order to maximize invention/innovation, taking into account the realities of research and development.

There is a growing sentiment that patents have changed the biotech (and pharmaceutical) research arena, removing its collegial spirit. It is only in recent years that patents have been used to seek rent from public research institutes and universities. Formerly, such use was considered to fall under an informal exemption by both industry and publicly funded researchers, but the position of industry is changing. Currently, when universities and public research institutes hold patents, they usually only seek licenses or royalties from industry (Grubb and Thomsen, 2010). Empirical observation indicates that the long-standing social norm that academic researchers share their information and tools is slowly fading under the influence of IP (Eisenberg, 2009). This change may be having a negative impact on the incentive to discover. Arguably, no state has a robust experimental use exception that reflects the long-standing social norm that existed among academic researchers, although this would make more sense than depending on noncompliance and nonenforcement.

IP Overlaps

A nexus of protection exists between all three main fields of IP. The copyright–patent overlap is apparent from the discussion above relating to the protection of software by both patent and copyright laws. The overlap is even greater in states that allow for online business method patents, such as the United States. For example, a method whereby the consumer receives a copyrighted product in exchange for viewing an advertisement was allowed patent protection, meaning that claims for software with the terms 'over the Internet' or at 'an Internet Web site' are sufficient to transform an unpatentable abstract idea into a patentable process (Ultramercial v. Hulu, 2013; on appeal to the Supreme Court). Most states consider such patents to be the mere performance of mental processes and not 'inventions' (Cornish et al., 2010).

Copyright and TM protections can also overlap. Certain signs may be copyright protected if they are 'works' and 'original' (Helfer and Austin, 2011). A short phrase (such as Exxon, *Exxon Corp v. Exxon Insurance Consultants Int'l Ltd*, 1982) is unlikely to be considered a literary work, but a longer slogan could be, or a design may be an artistic work. Copyright exists without registration, such that it is possible for TM owners to spontaneously bring copyright infringement claims, creating an overlap between the two forms of IP. There are benefits because copyright protects any reproduction, not limited to use in the course of trade, or use as a TM. At the same time, there are advantages in using TMs over copyright, because TMs offer potentially perpetual protection. For example, Disney has both copyright and TMs over many of its characters. Jane Ginsburg has argued that, in some cases, an author's name can function like a TM, identifying source and indicating quality, and a sign can identify the copyright owner, such that we should be open to allowing overlap (Ginsburg, 2008).

The widening of TM protection to include three-dimensional shapes (the most famous probably being the Coca Cola bottle) has resulted in controversy because of the overlap with patent law. Shape marks are also examples of when all three areas of IP may be implicated. For example, the

'Toilet Duck' bottle shape (for a toilet bowl cleanser) was designed and patented in the mid-1980s by Walter Düring. Any designs or models for the bottle could also have design rights (if registered) or copyright. Düring also has a registered TM for the words 'Toilet Duck' and figurative marks. The patent has since lapsed. Had Düring sought a three-dimensional TM for the bottle shape, a monopoly on the shape of the bottle would still exist. Thus, TMs that cover shapes with functionality potentially give perpetual patent-like protection.

A Look to the Future

Thinking about IP as encompassing only the classical fields of copyright, patents, and TMs is, of course, narrow. New forms of IP or neighboring or related rights continue to emerge. For example, TRIPS requires TM-like protection of GIs for wines and spirits even when there would be no misled public or unfair competition, even if the true origin is indicated, and if the GI is used with expressions such as 'kind,' 'style,' 'imitation,' or 'like.' Furthermore, TRIPS requires patent-like protection of plant varieties and protection of industrial designs and integrated circuits, databases enjoy *sui generis* protection in certain jurisdictions, WIPO has treaties for the protection of performers, and producers of phonograms (the fixation of sounds other than in cinematographic or other audiovisual work), broadcasters, and pharmaceutical companies are pushing for data exclusivity protection. These reflect the move toward protecting investment and the global inertia of assigning property to anything with commercial value.

At the same time, propertization of IP is being countered by the Development Agendas of WIPO and the United Nations, and by prodevelopment nongovernmental organizations, civil liberties groups, consumer advocates, and 'pirate parties' fighting copyright, for example. A trend toward the interdisciplinarity of IP with the fields of human rights, public health, and competition law is also starting to push against the reach of IP.

Finally, recent years have shown an increasing demand by indigenous peoples for protection of their traditional knowledge, traditional cultural expressions, and genetic resources. Closely connected to this are concerns about the relationship between climate change and patent law innovation policies, and the impact of climate change on indigenous peoples' interests.

The outcome of these movements will reveal itself over time, but it is clear that IP is indeed protean.

Abstract

A historical and comparative approach to the term 'intellectuals' or its equivalent in other languages shows the priority of the French use, in but also the persistent differences in its meaning even when translated in other contexts. The French model influenced other European countries, but it is only in Spain and Italy that the political mobilization of intellectuals was very similar to the French case. Whether in Russia (with the intelligentsia) or in German-speaking countries (with the Gebildete) or in the Anglo-Saxon world, the political, religious, and academic specifities remained very strong during the whole of the twentieth century.

The noun 'intellectuels' appeared in France in the 1890s and was largely diffused thanks to the polemics around the Dreyfus Affair (in particular the so-called '*Manifeste des intellectuels*,' published after the famous *J'accuse* paper by Zola issued on 13 January 1898, in *L'Aurore)*. This diffusion not only occurred in France but also, sooner or later, in the whole of Europe and even in America (North and South) (Drouin, 1994). There are two exceptions to this large diffusion of the new concept: Germany and Russia where there existed former and akin notions, *Intelligenz* and *intelligentsia*, already used as social or political denominations (Müller, 1971). Previous uses of the English translation, 'intellectuals,' are attested too before the 1890s, but they seem to have been too rare to have known a broad social circulation (Williams, 1976). In the same way, in America, 'intellectuals' became a common notion only in connection with newspaper commentaries about the Dreyfus Affair (Bender, 1987).

To understand why this new terminology received a European or even international diffusion, it is necessary to recall the issues of this historical moment. What was at stake in this crisis was not only a political problem but also the affirmation of a new group, defender of universal values against the reason of State (Charle, 1990). These values justified the fact that writers, artists, scholars, students, members of liberal professions, and so on, intervened on a collective basis in the political debate, although they were not themselves, for the main part, professional politicians. The other specificity of this moment was that, in other countries, this same cause or other similar ones favored the intervention of intellectuals, but generally in various patterns and with different contents. Since that period, social sciences have debated at a theoretical level, in order to find universal characteristics underlying this new vocabulary (Shils, 1972). As a matter of fact, the emergence of intellectuals cannot be assimilated to the apparition of a new permanent social group as some historians or sociologists suggest regularly, wrongly mixing intellectuals, intelligentsia and professions (Bell, 1973; Perkin, 1989). To know in reality what is meant by the words, intellectuals, *intellectuels*, *Intellektuelle*, *intellettuali*, *intelectuales*, and so on, it is necessary to define them within their specific cultural, social, and historical contexts.

The French Case

In France, even before the Dreyfus Affair, the neologism '*intellectuels*' was used by avant-garde circles as a social mark. The *intellectuel* was some kind of mandarin, who despised politics and wanted to distinguish himself from middle class, dominant writers and academics. *Intellectuel* was a sort of superlative of what Flaubert meant by the word '*artiste*' (Bourdieu, 1992). But, since the neologism was widely used during the Dreyfus Affair, the initial cultural meaning was replaced by a strong emphasis laid upon the political acception. In the first phase of the Dreyfus affair, the *intellectuels* were an equivalent of '*dreyfusards*' and, afterwards, when *antidreyfusard* intellectuals also intervened in a collective way, the word *intellectuels* began to define a special category of people who defended political positions based on arguments of social authority, i.e., their competence as thinkers, historians, scientists, professors, writers, or artists.

In France, the birth of *intellectuels* may be first explained by a growing inadequacy of former cultural patterns confronted to the buoyant cultural expansion of the last decades of the nineteenth century. Intellectual professions, far more numerous now, defended their social and symbolic status at once so that collective attitudes appeared, breaking with older individualistic habits. But this defense may be argued on two different grounds: with intellectual and pure values or on professional and pragmatic issues. Against avant-garde writers or academics, generally militating for the first option, professional associations appeared during the same period that were more attached to material interests. The first use of the term *intellectuels* was reserved for the first type of elitist fraternity. It was to be the germ of its political transformation as for the Russian *intelligentsia* diffused a bit earlier in the 1870s. As in Russia too, reformed universities played a major role in the process of emergence and mobilization of nonconformist intellectuals.

The second paradoxical factor of ideological and political change, was the early crisis of parliamentary democracy in France. After the stabilization of the Third Republic, apolitism predominated among intellectuals as if the end of history was already reached. A new politicization occurred with the crisis of official parties and the emergence of extremist factions, which

had a large echo among avant-garde writers (in particular anarchism and, to a lesser degree, socialism). This new trend prepared what is the specificity of the Dreyfus Affair, the invention of a new relationship with politics outside the official political scene. Intellectuals in this new terminology pretended to practice politics in a different way. This was possible because the legitimacy of Republican elite laid on the same bases as the legitimacy of intellectuals themselves, i.e., upon merit and individual talent. But in so far as these elite appeared incompetent or corrupted after different crises and scandals (Boulangism, Panama scandal, and so on), intellectuals preserved from these faults might pretend to offer an alternative elite necessary to lead any genuine democracy.

Students, avant-garde writers, and even younger generations of academics, before and during the Dreyfus Affair, expressed these new revendications of being the true representatives of the people against politicians. The State itself, with its growing intolerance towards literary innovations or extremist parties (especially anarchism) contributed to the mobilization of authors against juridical prosecutions through collective manifestos just before the Dreyfus affair.

The Dreyfus affair presented both a true continuity with preceding years and a break due to the scale of mobilization. Afterwards, the main following mobilizations of intellectuals obeyed the same collective rites and values (Ory and Sirinelli, 1986). Its founding importance was to prove that this type of mobilization might lead to real political consequences. This twofold mobilization (of *dreyfusards* and *antidreyfusards*) was new and defined, on both sides of the political scene, a general definition of intellectuals, which was not limited to leftist intellectuals. On the contrary in other countries, the equivalents of *intellectuels* are, generally speaking, confined to one side of the political spectrum.

The Peculiarities of English Intellectuals

In contrast with France, it is generally argued that no intellectuals exist at all, in the continental acception, in the UK. Since around 1980, British historians and sociologists reacted against this strong and vulgarized anti-intellectual bias. Some authors speak of an intelligentsia (Allen, 1986; Heyck, 1982), i.e., an elitist avant-garde, others of '*public moralists*,' which enhances the role of dominant and academic intellectuals (Collini, 1991) or of a '*professional class*' which assimilates intellectual professions to a new class (Perkin, 1989). A comparative approach shows that two specific factors may explain the strong difference with the French situation, in spite of the proximity of economic and political conditions in intellectual life, the persistent elitism of English academic life and the relative proximity between intellectual professions and political elite. Established elites, even if they were obliged to reform and enlarge the political system at the end of the nineteenth century, were not contested as an illegitimate power elite, to the degree they were in France. In fact, English dominant intellectuals mainly shared the same values and background as gentlemen and political leaders because they were largely issued from the same public schools and universities.

In front of these dominant intellectuals, appeared, in the last decades of the twentieth century, new types of intellectuals who presented outsider profiles. The best known were the Fabians who could not attend the best colleges and universities and had to find their way through journalism, literature, new academic institutions (e.g., the London School of Economics) or militant politics. But these avant-gardes were very different from contemporary French avant-gardes. They limited their intervention to one main field: for the Fabians, social and political questions, for aesthetes, aesthetic life, and so on. They pretended to create a voluntary structure and to indirectly influence the official sphere indirectly, not at all to destroy or affront it directly.

Even when mobilization occurred on a larger scale, as during the Boers war, English intellectuals used the official means of actions and respected legal frameworks. Finally, the main difference lay in the very different function of the State in England and in Continental Europe. In England, militant intellectuals endeavored to enlarge its role to correct social injustice, whereas, in France and even more in Germany, intellectuals tried first to weaken its authoritarian trends.

The German Case

Even if the word *Intellektuelle*, derived from French, continues almost until now to bear a derogatory nuance (Bering, 1978), the German genuine equivalents *Intelligenz*, *Gebildete*, and *Geistige*, have been used for a long time but do not imply, as the French term, the same political or social behaviors. This early appearance of the question of 'intellectuals' may be shown through the recurrent discussion about the academic proletariate (first in the *Vormärz* period, then in the 1880s, and finally in the Weimar period: Titze, 1990), with the ideological debates within the social-democratic party about the place of *Intelligenz* (Gilcher-Holthey, 1986), and also with the *Antisemitimusstreit* in 1879. This last famous polemic about the role of Jews in German society between the conservative historian Treitschke and his liberal colleague Mommsen, a former Forty-eighter (former participant to revolutionary troubles of 1848 in Germany), appears very near, in its arguments, to the debate between opposing French *dreyfusards* and *antidreyfusards*. The rights of minorities and, in particular, of individuals and Jews, lay at the center. Other affairs concerning academic freedom (Arons case or Spahn case), or freedom of creation, like the mobilization against the lex Heinze (1900), show too that the debates about intellectual autonomy were as crucial in Germany as in France and that they succeeded several times to mobilize some groups of intellectuals (Charle, 1996).

But, in all cases, mobilization was limited to specific groups and to particular issues which did not put into question the whole structure of State itself as in France. A mere political explanation (an Empire opposed to a Republic) does not suffice. What was specific and new in the Dreyfus case was the convergence of different intellectual groups about common values. In Germany, the corporatist ethos remained stronger even about general issues; free intellectuals and State intellectuals (mainly university professors) despised each other. Academics began at that time to live apart from the political sphere and preferred a general cultural function as State or *Bildung*'s defenders through different associations. Only a small

minority of free intellectuals and very few in the Academe put into question dominant elite or national causes.

The *Gebildete* assumed that they represented the true public opinion and that they were the best interpreters of general causes, but they intended to remain in their own field in order to serve their country best. This German intellectual and geographical fragmentation hindered the linkage between local or professional struggles for autonomy (Engelhardt, 1986; Hübinger and Mommsen, 1993; Ringer, 1969, 1992).

Southern Europe

In Spain as in Italy, the local equivalent of *intellectuels* seemed also to be in use in the 1890s in connection with, or even before, the Dreyfus case. The French example was very influential for the Spanish and Italian intellectuals because French cultural influence, in the two peninsulas, was already very strong since the French Revolution. Also, the inner social and political situations of Spanish and Italian intellectuals presented some analogies with the French context. As their French homologues, they thought that their countries went through a deep crisis (economic backwardness, military defeat in Spain, emigration, social riots and parliamentary corruption in Italy), which implied some sort of public intervention to find solutions. The strong anticlericalism and antimilitarism, the link between intellectuals and extreme left movements, the emergence of a new nationalism in both countries, also recalled the French debates at the turn of the twentieth century (Serrano and Salaün, 1988). Obvious differences also existed: the weaker public audience of intellectuals depending on the cultural backwardness of popular classes (high level of analphabetism) and the persistence of a large sector of opinion among Catholics, hostile to the cultural inheritance of Enlightenment, very influent in both countries, and an overproduction of *laureati* in Italy which could explain a strong commitment of academics to extremist parties (Barbagli, 1974, 1982; Michels, 1921).

Twentieth-Century Changes of Meanings

The intertwining of the sociological and the political or ethical viewpoints was perpetually renewed during the history of French intellectuals after the Dreyfus affair. A new sociologization of the word occurred with the attacks against previous *dreyfusards* in the pre-world-war period. The '*parti intellectuel*,' to use Péguy's phrase, was charged by their former allies (for example Georges Sorel) for having used the political struggle in order to conquer eminent positions of power. For their critics, this political party in fact constituted a social cluster of arrivists, a new elite of mandarins backing upon leftist politicians (Prochasson, 1992).

Between the two World Wars, there was a revival of the political and ideological emphasis on the meaning of the word during what has been called the 'Franco-french war' between the right-wing '*parti de l'intelligence*' and the left-wing '*intellectuels de gauche*.' This trend is enhanced because, at the same time, extreme left movements tried to restrict the notion to a sociological sense. The influence of Soviet Marxism may be found here in which *intellectuels* become a mere synonym for the Russian word *intelligentsia* which is nearer a sociological concept after the October revolution than the term *intellectuels* is in French. *Intellectuels* in the phraseology of the Communist Parties are assimilated to a social group in order to deny them any political autonomy and oblige them to define their political attitude within the limits of the Marxist-Leninist orthodoxy and to renounce to their own vision which is, in the French political tradition, far more linked with the French Revolution legacy and the defense of Human Rights (Benda, 1927). This intertwining of two traditions after the 1930s explains why leftist intellectuals used social concepts to attack their rightist opponents, while in contrast, rightist intellectuals laid the stress on the idealist conception of the intellectuals' role; they opposed themselves to materialism (i.e., leftist intellectuals influenced by Marxism) instead of only taking the defense of tradition as before (Sapiro, 1999).

The decline of Marxism in the *intelligentsia* and the excess of sociological terrorism in intellectual struggles during the 1950s and 1960s (Boschetti, 1985) explain why French contemporary intellectual life is dominated by some sort of revival of the primitive meaning of the word *intellectuel*. This complete historical cycle is one of the origins of the renewed interest for the study of intellectuals as political and social actors by French and foreign scholars in the 1980s and 1990s (Bourdieu, 1992; Jennings, 1993; Judt, 1992; Julliard and Winock, 1996; Sirinelli, 1990; Trebitsch and Granjon, 1998).

Anti-intellectualism, which was so frequent in England and Germany before World War I seemed to somewhat decline after the mobilization of all types of intellectuals (scholars as well as writers or journalists) during the *Union sacrée* for propaganda or practical applications devoted to National Defense. It conferred on them a new importance in all political contexts. After World War I, the democratization of politics, in both the UK and Weimar Germany, now placed intellectuals in a political context quite similar to the French one. The growing influence of left parties, of Marxist ideas, of international questions (communism, fascism, pacifism, fear for a new world war) gave birth to international debates among European intellectuals (or even American, if the case of New York intellectuals may be included: Wald, 1987). Nevertheless, this did not mean that the specific national traditions were forgotten. Even if notions like *Intellektuelle* or *intelligentsia* were present more than before in the German or English public debate, they never obtained the general influence or consensus which their equivalents enjoyed in France, Italy, or Spain (Bering, 1978; Stark, 1984). Even innovative sociologists such as Karl Mannheim continued in general to use the older lexis even to propose their new conceptions of a free-floating intelligentsia (*freischwebende Intelligenz*: Mannheim, 1929). Debates about the social decline of 'intellectual workers' in Germany or Central Europe used too old phrases such as *geistige Arbeiter* (Jarausch, 1990, Titze, 1990). The anti-intellectualism of the Nazi movement and the huge migration (after 1933) of progressist or Jewish intellectuals out of Germany and Central Europe stopped, for almost two decades, this timid convergence with the Latin tradition of intellectuals.

The decline and fall of the different fascist or communist regimes in the second half of the twentieth century gave a new

actuality to the oppositional figure of intellectuals, in particular in Central and Eastern Europe (the 'dissidents' who recalled the nineteenth century meaning of intelligentsia). In Southern Europe, in Africa, Asia, or Latin America, revolutionary intellectuals or militants for the Human Rights also rejuvenated the nineteenth century European tradition of intellectual youth mobilized for the nation or populist projects. All these convergences or political cycles explain why the historical notion of intellectuals continues to be at the center of many historical, sociological, or philosophical reflexions, trying until today to find general or transhistorical definitions of this term.

Intellectuals, Sociology of

Robert J Brym, University of Toronto, Toronto, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

This article first reviews the development of the term 'intellectual' and the social and historical circumstances that led intellectuals to become a large, moderately well-defined, and occasionally self-conscious group. Particular attention is paid to the rise of commerce and industry since the late Middle Ages, the spread of literacy, the growth of markets, and the proliferation of social contexts for intellectual discussion and debate. The article then argues that three main traditions of analysis inform the sociological study of intellectuals: class theories, theories of classlessness, and theories of shifting social networks. It is argued that the third of these traditions is the most fruitful. Evidence to support this claim is drawn from analyses of the social conditions that lead intellectuals to assume various ideological and political positions. It is concluded that, to explain intellectuals' allegiances, one must trace their paths of social mobility as they are shaped by the capacity of various social collectivities to expand the institutional milieus through which intellectuals pass. To the degree these milieus are imprinted with the interests of the social collectivities that control them, they circumscribe the interests reflected in intellectuals' ideologies and political allegiances.

Definition

Intellectuals are people who produce, evaluate, and distribute culture. Their role often involves some mixture of endorsing or criticizing the cultural objects of their attention. Following Michael Burawoy (2005), intellectual work may be said to vary along two dimensions: its intended audience (which may include academics, policy makers, various sections of the public, and the public as a whole) and the degree to which it makes instrumental versus normative claims ('what is' versus 'what ought to be'). Individual intellectuals may specialize in one or more of the cells resulting from the cross-classification of the two dimensions. Similarly, particular academic disciplines, professions, schools of thought, regions, and historical periods may highlight one or more specializations (Brym and Nakhaie, 2009).

Origins

The intellectual role has been performed in all societies. Even a nomadic tribe of fewer than 100 foragers could afford to employ a shaman to forecast the weather, predict the movement of animals, and tend to the ill. However, the Renaissance humanists (CE *c.*1300–1600) were the first influential group resembling today's intellectuals. Renaissance scholars thought they lived in a golden age of virtue and learning. To emphasize the point, they invented the term 'Middle Ages' to refer to the dark gulf separating their era from the glories of the ancient world. Promoting the study of poetry, grammar, rhetoric, history, and moral philosophy, the humanists from Petrarch in the fourteenth century to More, Erasmus, and Rabelais in the sixteenth century influenced the Reformation, the scientific revolution, and the Age of Reason.

Only since about 1600, however, have intellectuals become a large, moderately well-defined, and occasionally self-conscious group. The chief factors that helped to distinguish them were the rise of commerce and industry since the late Middle Ages, the spread of literacy, the growth of markets, and the proliferation of social contexts for intellectual discussion and debate. Flourishing commerce and industry permitted the accumulation of economic surpluses. They were used to expand state and private institutions employing intellectuals. Public education and mass literacy increased demand for intellectual services. In turn, the evolution of markets for these services allowed intellectuals greater freedom to define their political allegiances. The interests of aristocratic and church patrons no longer tightly constrained them. Finally, a host of modern social settings – ranging from universities to political movements, professional societies to coffee houses, academic journals to mass-circulation newspapers – provided contexts within which intellectuals could formulate their social and political identities.

It was not until the second half of the nineteenth century that 'intellectual' and the kindred 'intelligentsia' entered common parlance. The term 'intellectual' was first employed on a wide scale in France. In 1898, Georges Clemenceau referred to the leaders of the anticlerical and antimilitary camp that opposed the conduct of the Dreyfus trial as *les intellectuels*. Soon, the political right was deriding the self-proclaimed conscience of the French nation. Because of the resulting public debate, the term 'intellectual' stuck. The term 'intelligentsia' was popularized in Central and Eastern Europe a few decades earlier. It, too, denoted liberals, socialists, and other critics of authority. Only gradually since the end of the nineteenth century has the term 'intellectual' gained widespread acceptance and succeeded in unwrapping itself from quotation marks.

Theories

Many normative or moralistic treatments of the problem of intellectuals may be found in the literature. They criticize what intellectuals do and make a case for what they ought to do. Julien Benda (1969[1928]), Noam Chomsky (1969), and others have written important works in this tradition. In contrast, this article focuses on the analytical literature, which seeks to explain why intellectuals do what they do.

Three main analytical traditions inform the sociological study of intellectuals. Sociologists have regarded intellectuals as

(1) members of a class or as a class in their own right; (2) relatively classless; and (3) embedded in a shifting network of class and other group affiliations (Brym, 2010[1980]; Kurzman and Owens, 2002).

Class Theory

Karl Marx and Friedrich Engels (1972[1848]) regarded intellectuals as members of the *petite bourgeoisie* who would be 'precipitated into the proletariat' as capitalism developed. They believed that, under socialism, classes would disappear, so one could be "a farmer in the morning, a laborer in the afternoon, and a philosopher in the evening" (1972 [1845–6]). In contrast, anarchists – Mikhail Bakunin (1872) and Jan Wacław Machajski (Shatz, 1989) chief among them – asserted that intellectuals aspired to form a dominant class. In making this claim, they anticipated the ideas of many twentieth-century social thinkers.

By the 1950s, the middle of the class structure had expanded enormously in both capitalist and self-proclaimed socialist societies. People with university degrees filled many of the intermediate ranks. Reflecting on this change, a growing number of social thinkers argued that intellectuals constitute a class that enjoys increasing power. Alvin Gouldner (1979) held that intellectuals comprise a new 'emancipatory class.' Barbara Ehrenreich and John Ehrenreich (1979) maintained that intellectuals form part of a new 'professional-managerial class.' Irving Kristol (1972) called intellectuals the "new class of knowledge workers." Defining intellectuals broadly to include economists, technocrats, administrators, police bureaucrats, ideologists, scientists, and artists, Georg Konrad and Iván Szelényi (1979) went so far as to claim that Eastern European intellectuals had assumed class power. These and other scholars, including James Burnham (1941), Milovan Djilas (1957), and John Kenneth Galbraith (1967), disagreed about much, but they shared the view that intellectuals form a large, ideologically quite homogenous, and rising or dominant class.

Steven Brint's research exemplifies one important criticism of the view that intellectuals form a class. Using American data from a series of General Social Surveys, he demonstrated considerable ideological heterogeneity and strong cohort effects among intellectuals. Intellectuals, it turns out, are as numerous on the right as they are on the left, with the two camps tending to cluster in different occupational niches. Moreover, their ideological predispositions depend partly on the *Zeitgeist* of the historical period during which they reach late adolescence and early adulthood (Brint, 1984). Consequently, the ideological cohesiveness and presumed teleological movement of intellectuals toward class power seem greatly exaggerated.

The second main criticism of the argument that intellectuals form a rising or dominant class is that, typically, they are demonstrably subservient to other economic and/or political classes. The Communist Party of the Soviet Union always sought to ensure that universities, research institutes, and the *nomenklatura* were populated by loyalists. In Russia, the collapse of communism witnessed the ascent not of intellectuals but of people with strong connections to the state security apparatus and organized crime. Lawrence King and Iván Szelényi (2004) anticipate that, in capitalist societies, intellectuals will come to dominate an increasingly autonomous state. However, this eventuality seems increasingly unlikely in an era when giant global corporations influence governments to eliminate trade barriers and give up sovereign rights to pro-free market transnational organizations such as the World Bank and the International Monetary Fund. State autonomy has decreased in recent decades and there can be little doubt which socioeconomic strata are chiefly responsible for this development.

For a time, intellectuals were politically ascendant in some parts of the world. For instance, as Charles Kurzman (2008) has shown, between 1905 and 1911, more than a quarter of the world's population (in China, Iran, Mexico, the countries of the Ottoman Empire, Portugal, and Russia) was caught up in democratic revolutions led largely by self-identified intellectuals. Many workers, peasants, members of the bourgeoisie, and in some cases even landlords deferred to them. Within a few years, however, their ascent was checked. Russian workers wanted more than just elections and a constitution. Chinese intellectuals lost power to the army because of widespread social disorder. When their commercial interests were threatened, the great powers turned against new, democratic regimes. Among the countries listed earlier, only Portugal's democratic constitution survived, and then only until 1926.

Theories of Classlessness

Karl Mannheim (1955[1929]) held that modern intellectuals form neither a class nor part of a class. Instead, they are "members of a relatively classless stratum which is not too firmly embedded in the social order." Mannheim acknowledged that intellectuals are typically recruited from various classes. However, he also held that, because intellectuals participate in a common educational milieu, their class differences, and the variations in outlook normally associated with them, tend to be suppressed. Many scholars echoed Mannheim's conclusions. Talcott Parsons (1963) asserted that intellectuals put 'cultural considerations before social ones.' Everett Ladd and Seymour Martin Lipset (1975) wrote that the capacity of intellectuals for social criticism, creativity, innovation, and attention to facts enables them to overcome their class socialization – and, for that matter, the socializing influence of many other social collectivities to which they belong.

A recent and more nuanced variant of the classlessness thesis has been proposed by Neil Gross (2002, 2008). Gross does not regard intellectuals as entirely removed from the sway of social forces but nonetheless emphasizes that ideological and intellectual choices are largely a function of which ideas resonate with intellectuals' self-conceptions. However, this approach begs the question of how self-conceptions are rooted in social experience. Categories such as 'class,' 'ethnicity,' and 'gender' are admittedly too broad and static to capture the range of social forces that influence intellectuals' political and other choices, but acknowledging this fact does not necessitate a retreat to an explanatory framework that emphasizes coincidence or a voluntaristic phenomenology of self. Instead, it suggests the importance

of discovering more precise and dynamic social variables that influence intellectual choice.

Theories of Shifting Social Networks

Both class theories and theories of classlessness ignore crucial issues. Notably, intellectuals may be found at all points on the political spectrum. Class theories may briefly note ideological heterogeneity but tend to dismiss it as an uninteresting side issue, leaving it unexplained. Meanwhile, theories of classlessness minimize the significance of social influences on the shaping of ideas, thereby deflecting attention from the very issue that the sociology of intellectuals is mandated to analyze.

A third approach seeks to overcome both these problems by focusing on the intellectual's web of shifting group affiliations. According to Pierre Bourdieu (1984[1979]; Bourdieu and Wacquant, 1992), cultural fields tie individual and organizational actors together in various social institutions. These cultural fields are structured as social networks. Different positions in a social network are associated with different endowments of economic, social, cultural, and intellectual capital. Network position is also associated with cognitive structure. Thus, intellectuals in similar network positions share tastes, ideas, and values (Anheier et al., 1995; Lamont, 1987).

Randall Collins's magnificent analysis of philosophical schools takes this argument a step farther by showing how intellectuals gain reputations by successfully competing for attention, fame, and influence in intellectual networks. Collins demonstrates that intellectual creativity flows through chains of personal contacts. It moves by structured rivalries between intellectual networks. And it flowers when rival circles intersect in cultural metropoles. Because 'intellectual attention space' is limited, no more than six, and often as few as three, creative schools manage to propagate their ideas across generations in a given culture at a given time. Creativity dries up when a single orthodoxy dominates. Contrariwise, intellectuals create new schools of thought in response to political and economic changes that shift the distribution of material resources needed to support their work. The stars of intellectual life tend to be people who are involved in, or close to, such organizational transformations. Leading innovators are as likely to be conservatives as radicals (Collins, 1998; Gross and Frickel, 2005).

Bourdieu's and Collins's mesolevel theories are compatible with Robert Brym's approach, which, however, focuses on political allegiance rather than intellectual creativity and influence. Developing themes in Antonio Gramsci's essay on intellectuals (Gramsci, 1971[1929–35]), Brym argues that the ideologies and political allegiances of intellectuals depend on their social origins and the structure of opportunities for education, employment, and political involvement they face during their careers. These opportunity structures are, in turn, shaped by the relative power of major classes and other social collectivities. Accordingly, to explain intellectuals' ideologies and political allegiances, one must trace their paths of social mobility as they are shaped by the capacity of classes, ethnic groups, religious orders, and other social collectivities to expand the institutional milieus through which intellectuals pass. To the degree these milieus are imprinted with the interests of the collectivities that control them, they circumscribe the collective interests reflected in intellectuals' ideological and political allegiances. From this point of view, it is an oversimplification to say that intellectuals form a class, are members of a class, or are classless. They are embedded in social networks whose ties to various classes and other collectivities shift over time and help account for their ideologies and political allegiances (Brym, 1978, 2010 [[1980]]). This theme has also been taken up by Jerome Karabel (1996). The remainder of this article illustrates it.

Social Origins and Institutional Opportunities

Social Origins

In Weimar Germany, professors were largely antirepublican and right-wing. Mostly, their fathers were military officers, state bureaucrats, and academics, members or handmaidens of the aristocracy. In contrast, nonacademic intellectuals were inclined to the left. They tended to be children of successful participants in the industrial revolution, members of the upstart German bourgeoisie. Similarly, in the middle of the nineteenth century, Russia's conservative and politically moderate intellectuals were recruited overwhelmingly from the aristocracy. On the other hand, the first generation of truly radical Russian intellectuals dates from the 1860s, and it contained in its ranks a large mixture of commoners. Their fathers were merchants, peasants, and petty officials. These examples illustrate that support for the traditional social order is common among intellectuals who have been reared in upper class families that are threatened by social change. Being born into a less advantaged class has usually been associated with greater potential for intellectual radicalism.

But not always. In North America, it seems that rates of upward social mobility have historically been higher than in Europe, and class has been a less important social distinction. As a result, class origin has less bearing on the ideologies and political allegiances of North American than European intellectuals. Especially in the United States, ethnic and racial origin, educational background, field of expertise, professional and institutional status, and generational experience matter more. Accordingly, American surveys show that professors in small provincial universities are more likely to be politically conservative than are professors in prestigious Ivy League universities. African-American and Jewish intellectuals are usually more left-wing than are non-Jewish white intellectuals. Young intellectuals who work in the social sciences and cultural fields are more likely to be left-wing than are older intellectuals with business affiliations (Ladd and Lipset, 1975).

Economic Opportunities

As intellectuals reach adulthood and enter the job market, the structure of markets for intellectuals skills can modify their early political socialization. An abundance of secure jobs that

allow free expression can dampen intellectuals' early radical impulses. A lack of such jobs can exert a radicalizing effect. Some intellectuals may continue to express radical political sentiments after they have taken jobs that suit them professionally. Still, the rate and intensity of radicalism are generally greater when the number of such jobs is fewer.

For example, the Quebec educational system began to produce substantial numbers of highly educated French-speaking graduates in the 1960s. The new graduates found that an English-speaking minority controlled the larger and more efficient businesses in the private sector of the economy. Many highly educated Québécois were shut out of good jobs. This, among other factors, encouraged some of them to develop the idea that to become 'masters in their own house' Quebec must become a sovereign state. Surveys show that intellectuals became separatists in disproportionately large numbers and were a driving force leading to the election of separatist governments in 1976 and 1994.

Political Opportunities

The patterns of political opportunities intellectuals face also profoundly affect their ideas and loyalties.

At the level of social organization, political opportunities are structured by the availability of historical agents: workers, peasants, ethnic collectivities, and other groups that intellectuals may demarcate as the chief instruments of social change. Whether intellectuals become, say, socialists, populists, or nationalists is determined partly by which historical agents are mobilized for political action and which are relatively politically dormant in intellectuals' milieus at a given time.

At the level of the political system, the capacity of party organizations to absorb new talent is also important in shaping intellectuals' allegiances. For example, before the 1920s, the German Social Democratic Party had attracted most of the country's radical intellectuals. By the 1920s, however, it became (to use the then-current catchwords) 'bossified, ossified, and bourgeoisified.' Old men remained incumbents in the German Social Democratic Party for many years. Young men had little hope of rising in its ranks. Young women were even less likely to ascend to prominence, hindered as they were by the institutionalized inequality and sexism that, as Dale Spender (1982) documents, has dominated intellectual life for centuries. Lack of opportunity was one reason the young generation of radicals turned in large numbers to the Communist Party of Germany.

If historical agents are largely unmobilized and no party organization is available to sustain the intellectual's beliefs, a process of political disillusionment is likely to set in. The lack of an historical agent combined with the presence of a party organization, however, is likely to lead to intellectual elitism.

Intellectual Elitism

Ever since Plato envisaged a society ruled by 'philosopher-kings,' some intellectuals have been motivated by the conviction that they are better suited than are nonintellectuals to create and maintain ideal social arrangements. For example, in 1816, Hegel referred to Prussia as "the state of the intelligentsia." Both he and Comte characterized historical epochs as accomplishments of the human mind, which they saw as the driving force of history. In their judgment, the intellectual was the human mind's personification. Reinforcing this elitist view was the late nineteenth and early twentieth-century conception of scientists and other highly educated experts as a sort of ascetic priesthood whose dispassionate approach to their subject matter allowed them to perform extraordinary cognitive feats promoting the progress of humanity.

Lewis Feuer's studies did much to dispel the supposed ascetic roots of modern science, emphasized by Max Weber and Robert Merton, and demonstrate the antiauthoritarian, hedonistic, and individualistic mind-set that typically accompanies creative scientific work (Feuer, 1963; Merton, 1936; Weber, 1958[1905]). In recent decades, scholars working in the hybrid field known as 'social studies of science' have succeeded in bringing intellectual creativity even more firmly down to earth by demonstrating how (to quote Steven Shapin) science is "produced by people with bodies, situated in time, space, culture, and society, and struggling for credibility and authority" (Shapin, 2010; Johnson, 2008).

Turning to politics, the degree of elitism expressed by intellectuals varies independently of their position on the left–right dimension. One finds democrats and elitists on both the left and the right. Two sets of circumstances promote intellectual elitism – weak participatory demands by the masses and lack of competition from other elites.

The history of Latin America illustrates how weak mass demand for political participation encourages intellectual elitism. For example, in the 1950s, Cuban revolutionary intellectuals were faced with a small and reformist working class and a politically inert peasantry. Consequently, they took matters into their own hands, forming guerilla bands in the countryside to seize state power. The low level of popular political participation in, and mass control over, the Cuban revolutionary party diminished the likelihood of subsequent democratic development.

The history of socialism and communism in Russia reveals a similar pattern. However, the Russian case is also instructive because it illustrates the opposite tendency. Even apparently unyielding elitists can democratize if they are pressured from below. Thus, when ties between workers and Russian Marxist intellectuals were dense – during the strike wave of the 1890s, the 1905 revolution, and the period of labor militancy in 1912–14 – most intellectuals wanted their parties to operate according to democratic principles. In contrast, when working class political participation fell – due to labor quiescence caused by troughs in the business cycle, strong government and police reaction to radical activities, and enormous losses in World War I – intellectuals returned to elitist principles of party organization.

A second precondition of democratic practice among intellectuals is vigorous elite competition. Aristotle argued

that justice can be maximized not if philosopher-kings rule, but if constitutions are divided against themselves – if, in other words, there exists what is now called a separation of powers among the branches of government. Following Aristotle, scholars now commonly believe that tyranny and arbitrary rule by an elite can be prevented if the branches of government hold each other in check. One may invoke a broadly similar principle in analyzing intellectual elitism. Nonintellectual elites need to keep intellectuals in check if they are to prevent the political and social dangers that can result from intellectuals taking Plato to heart.

The most compelling case for the benefits of elite competition derives from the history of communism, the epitome of intellectual tyranny in the twentieth century. Yet the dangers of intellectual elitism have hardly subsided now that the communist era has virtually ended. In much of the world, intellectuals are making bolder claims than ever about their ability to forecast and plan social and scientific change. Governments are respecting those claims by seeking the advice of intellectuals, awarding them research contracts, and employing them by the legion. Emboldened by their growing numbers and prestige, some intellectuals, particularly in the United States and Eastern Europe, have proclaimed themselves the ruling class of the future, the real holders of power in an era when knowledge allegedly means more than capital in determining status.

One should not take intellectuals' claims about their accomplishments too seriously. For example, as Eva Etzioni-Halevy (1985) documents, economists, the 'hardest' of the social scientists, have generally failed to forecast and regulate economic trends. Natural scientists have arguably helped to create nearly as many social problems as they have solved.

On the other hand, the dangers of too much intellectual influence on political life should be carefully heeded. Individual intellectuals have proved to be exemplary political leaders, but when intellectuals are in a position to impose their blueprints on society they often do more harm than good. The 'shock therapy' advocated by the academics who formed the core of the Russian government late in 1991 caused tremendous social dislocation and political reaction that undermined reform in that country. This is only one example of what can happen when intellectuals rule. It seems reasonable to conclude that the practice of politics is much too serious a matter to be left only to the intellectuals.

Abstract

Intelligence is one of the most talked about, researched, and measured of the many psychological constructs describing individual differences. Intelligence tests but have undergone considerable changes over the past 100 years as our models of intelligence have become more refined and data based. This article overviews some of the more notable developments in defining and assessing intelligence, examples of currently used tests followed by a discussion of their uses.

"A rose by any other name…" Past and modern civilizations or countries have created words and descriptions that reflect individual differences in the abilities that we now have come to label as intelligence in the Western world. Intelligence, no matter the differing views on its 'structure' or 'cause,' is a major factor underlying individual differences in what and how we think, know, act, feel, learn, and solve problems. Importantly, this ability is universal and variations within and between persons and groups can be measured.

This article reviews the foundations of intelligence including definitions, types of intelligences, historical and contemporary understandings of the construct, and current models. Following a brief presentation of some of the tests that have been employed for assessing cognitive abilities, the article will highlight two of the more popular intelligence tests and focus on how the results help us to understand individual differences in intelligence. Finally, consideration of some important social and professional issues will be summarized.

What Is Intelligence?

Agreement on a description of intelligence has been challenging. Indeed, asking the seemingly simple question of 'what is intelligence?' results in varied responses. The differing descriptions of intelligence reflect the diverse nature of this concept and the ways in which it may be defined. The question may lead to several additional queries: (1) What is intelligence? (2) Are there different kinds of intelligence? (3) What causes intelligence? (4) Can we measure intelligence? and (5) How does intelligence help us to explain individual differences? Much of the psychological literature addresses these very questions (e.g., Neisser et al., 1996).

Various theories have been proposed to describe and define intelligence. Some theories define intelligence as a composite of many correlated specific abilities (e.g., Spearman, 1904), while others suggest there are different 'kinds' of intelligence (e.g., Gardner, 1983) ranging from verbal-linguistic to interpersonal intelligence. A public statement published by 52 experts (Gottfredson, 1997, p. 14) defined intelligence as a general mental capacity that includes the ability to think logically and abstractly, understand complex ideas, reason, plan, solve problems, learn quickly and from experience, communicate, and problem-solve (Gottfredson, 2008; Gottfredson and Saklofske, 2009). A further analysis of the 'knowns and unknowns' about intelligence was published 2 years later by Neisser et al. (1996) where it was recognized that both genetics and environment are determiners of intelligence, gender differences were generally small or nonsignificant in contrast to group differences, and intelligence was an important predictor of school achievement and years of education.

Brief History of Intelligence Assessment

Although there are examples of efforts to measure intelligence dating back several 1000 years, the establishment of psychology as a scientific discipline and practice provided the framework for modern intelligence assessment. In the mid- to late-1800s, the well-known Galton tests including strength of grip, memory for digits, pitch discrimination, and form boards were the standard tools for assessing intelligence (Galton, 1885, 1887). However, the first comprehensive measure of intelligence was published by Binet and Simon (1905). Initially developed for use with French school children to determine who may benefit from 'special education,' the measure consisted of 30 tasks that were sequenced in order of difficulty.

It was this initial endeavor to evaluate the mental abilities of individuals that has driven the cognitive-intelligence assessment movement. Revisions to the Binet and Simon scale in 1908 reformulated the measure so that the tasks were organized into age levels, providing a basis of comparison by which a child's performance could be evaluated against others of their same age. In addition, this revision produced a quantification of the child's performance in terms of an intelligence quotient or 'IQ' described by Stern (1912). This Binet measure gained much popularity in Europe, and was the impetus for the expansion of intelligence assessment once it was translated to English and introduced to North America by Henry Goddard. Lewis Terman (1916) developed the Stanford–Binet Intelligence Scale, which became the primary individually administered test for assessing intelligence.

A major advancement in intelligence assessment came during World War I when the United States developed the Army Alpha and Army Beta tests under the direction of Robert Yerkes (Yerkes, 1921). Designed to evaluate the cognitive intelligence of potential soldiers, the Group Examination Alpha (Army Alpha) measure was designed to assess literate

English speakers, whereas Group Examination Beta (Army Beta) evaluated illiterate or non-English speakers. The results of these group-based measures then informed decisions regarding suitability for wartime selection assignment of recruits.

Following his experiences with these early tests, David Wechsler developed the first of what is currently the most frequently used family of intelligence assessment measures by combining the verbal and nonverbal components of the two separate Army measures into a unitary assessment tool. The Wechsler–Bellevue (Wechsler, 1939) initially measured child and adult intelligence but has since been separated into adult, child, and preschool scales, each of which has undergone several revisions to update the subtests and items, revise and expand the factor structure, and update norms for each test. Many other intelligence tests have appeared during the twentieth century, some being variations on the Wechsler type tests, while others are based on different theoretical models or for other purposes (e.g., cross-cultural assessment, assessing hearing or visually impaired children).

Models for Describing Intelligence

Approaches to assessment of cognitive intelligence have typically followed from psychological theory on the broad topic of 'what constitutes human intelligence?' This topic has produced a number of long-standing debates that continue to this day. The primary discussion concerns the existence and importance of what is commonly referred to as the 'general factor of intelligence' or '*g*.' In essence, *g* refers to a statistical and theoretical convergence of performance on different measures of intelligence. As such, it is indicative of an individual's overall cognitive ability, regardless of the task by which cognitive intelligence is measured. It was initially proposed by Spearman (1904), who reported a series of significant positive intercorrelations (relationships) among various tasks that were thought to measure unrelated aspects of intelligence. Spearman proposed that all branches of intellectual activity have one fundamental function (or group of functions) in common (Spearman, 1904, p. 284). Indeed, proponents of *g* state that humans demonstrate a statistically measurable overarching level of cognitive ability, and then utilize that ability when completing individual cognitive tasks.

In contrast to this perspective, critics of *g* have cited contrary evidence of divergence in cognitive abilities (Thorndike et al., 1909) initially reflected in the description and assessment of 'primary mental abilities' by Thurstone (1938). Rather than supporting a unitary factor of intelligence, this alternative approach emphasizes the uniquely separate (or *s*) abilities such as mathematics, processing speed, or visual-spatial scanning.

Current perspectives on intelligence tend to identify the unique properties of both *g* and *s*, and highlight the interplay between an individual's unique performance on some tasks (or related tasks) and their statistically calculated overall performance, typically referred to as Full Scale Intelligence (FSIQ), which is taken to represent *g*.

While there are other viable models of intelligence including Piagetian and neo-Piagetian, neuropsychological, and chronometric descriptions, four contemporary theoretical models of intelligence will be briefly described with the aim of highlighting their core features and how this is then used in assessing intelligence. Specifically, we will review the current factor structure of the Wechsler family of cognitive abilities; the Cattell–Horn–Carroll (CHC) factor theory; the Planning, Attention Simultaneous, and Successive (PASS) theory; and Sternberg's Triarchic Theory of Intelligence.

Wechsler Factor Structure

The forthcoming *Wechsler Intelligence Scale for Children, 5th Edition* (WISC-V; Wechsler, 2014) and the current *Wechsler Adult Intelligence Scale, 4th Edition* (WAIS-IV; Wechsler, 2008) and *Wechsler Preschool and Primary Scales of Intelligence, 4th Edition* (WPPSI-IV, Wechsler, 2012) all incorporate *g* as a unitary indicator of overall global intelligence as represented by the FSIQ from each measure. In addition, the developers of the measures have painstakingly undertaken statistical analysis to determine the exact and specific underlying framework by which the individual subtests may be combined to provide an additional level of analysis between FSIQ (*g*) and the subtests (*s*). As such, psychologists are aware of the unique factor structure of each of the Wechsler measures and the resulting framework for understanding and interpreting the unique properties of cognitive intelligence demonstrated by an individual's performance on a standard administration of a measure.

Past versions of the Wechsler measures incorporated a verbal–nonverbal split as the main secondary factors subsumed by the FSIQ. Specifically, verbal abilities were represented by the Verbal IQ (VIQ) and nonverbal abilities by the Performance IQ (PIQ). These two domains were subsequently populated by subtests that were statistically shown (through factor analysis) to be strongly related to each other, and less related to subtests subsumed by the other factor. The current editions of the three measures have utilized new statistical data to support the adoption of a broader factor structure. Specifically, the WISC-V utilizes a five-factor structure with verbal abilities being represented by the Verbal Comprehension Index (VCI), visual-spatial abilities represented by the Visual-Spatial Index (VSI), fluid reasoning abilities represented by the Fluid Reasoning Index (FRI), the ability to maintain and mentally manipulate information in memory represented by the Working Memory Index (WMI), and speed of information processing by the Processing Speed Index (PSI). Conversely, the WAIS-IV uses a four-factor structure that includes the VCI, WMI, and PSI in addition to nonverbal (perceptual) reasoning abilities represented by the Perceptual Reasoning Index (PRI). The WPPSI-IV utilizes a three-factor structure (VCI, WMI, and VSI) or a five-factor structure (VCI, VSI, FRI, WMI, and PSI) depending upon the age of the child examinee.

Although some cognitive theorists argue against the factor structure of the Wechsler measures as pure indicators of human cognitive abilities (e.g., Benson et al., 2010), the Wechsler tests have received continued empirical support and are the most frequently used measures in clinical practice and research contexts. The scales have been standardized in many countries around the world and evidence suggests that the structure of the test holds up well in different countries (e.g., Georgas et al., 2003).

CHC Theory

The CHC model of human cognitive abilities is the most statistically rigorous theoretical explanation of human cognitive abilities. Similar to the Wechsler framework, CHC theory recognizes an overall level of cognitive ability that results from the overlap or correlation between the identified specific abilities. The major difference is the identification of the major broad factors that form the foundation of the Woodcock–Johnson Tests of Cognitive Abilities.

More specifically, CHC theory is a blending of two predominant theoretical frameworks. The Cattell–Horn model posits a primary division of human cognitive abilities on the basis of 'crystallized intelligence,' or the use of acquired knowledge, and 'fluid intelligence,' or abstract reasoning and problem solving. Initially, Raymond Cattell (1941, 1943) analyzed a large data collection representing numerous different tasks of intellectual abilities, the results of which indicated that tasks that tap crystallized intelligence are generally similar, whereas performance on tasks of fluid intelligence is also similar but distinct from crystallized intelligence tasks. Cattell began the tradition of utilizing specific notation to represent the different cognitive factors with a capital 'G' to represent general intelligence in combination with a lower case letter (e.g., *c* for crystallized or *f* for fluid) to represent the factors. Subsequent to this early description of G*c* and G*f*, John Horn (1965) expanded Cattell's theory to identify and include other factors such as cognitive speed (G*s*) and visual-spatial ability (G*v*). Additional research conducted over the next two decades continued to support and refine this model, with 10 unique factors being described by the 1990s (Schneider and McGrew, 2012).

Building upon this initial framework, John Carroll (1993) conducted a massive reanalysis of over 450 unique data sets on human cognitive abilities that resulted in a three-stratum model of human intelligence. In short, stratum III is the highest level, and is considered to represent *g*. Stratum II consists of the specific broad factors as initially described by Cattell and Horn. However, Carroll's reanalysis produced some modifications from Cattell and Horn's factors, with the resulting eight factors being crystallized intelligence (G*c*), fluid intelligence (G*f*), memory and learning (G*γ*), visual perception (G*v*), auditory perception (G*a*), long-term retrieval (G*lr*), cognitive speediness (G*s*), and reaction time/decision speed (G*t*). Finally, stratum I consists of several narrow abilities that are subsumed by each stratum II factor.

To date, the CHC model of human cognitive abilities is widely considered to be the most accurate representation of intelligence as measured by current cognitive tasks. It has been adapted for clinical use in the current third edition of the *Woodcock–Johnson Tests of Cognitive Abilities* (WJ-III Cog; Woodcock et al., 2001) and soon to be published fourth edition (WJ-IV Cog; Schrank, McGrew, Mather, 2014).

PASS Theory

The PASS theory of intelligence is rooted in Luria's work on brain structures and functionality (Luria, 1966, 1973a, 1973b). Luria posited that human cognition can be described as a system of three distinct yet related functional units (attention-arousal, processing and memory, and behavioral regulation) that support four psychological processes (Luria, 1973b). In turn, these four processes form a 'working constellation' of cognitive activity, which may enable different people to be successful on cognitive tasks via different cognitive processes (Luria, 1966, p. 70).

The first process in the PASS framework is Planning, which is the capacity to create, implement, and evaluate strategies to complete tasks effectively (Naglieri et al., 2012a). In effect, planning enables an individual to solve a problem and controls the other three processes. Attention involves vigilance, alertness, focus, and mental orientation to a stimulus over time and the resistance to distraction. Simultaneous Processing involves the mental integration of information into a whole and is often, though not solely, utilized in visual-spatial tasks. Conversely, Successive Processing is used to organize information into a sequential order and is more often associated with verbal information processing and reading.

The PASS theory of intelligence is operationalized by the Cognitive Assessment System–Second Edition (CAS2; Naglieri et al., 2012b) and has been found useful in the identification of children with disorders of attention or reading (Naglieri et al., 2012a). The second edition of the Kaufman Assessment Battery for Children (KABC-II; Kaufman, 2004) is another test that can be scored according to the Luria model as well as the CHC model described above.

Sternberg's Triarchic Theory

In comparison to the above models that describe cognitive abilities as factors, Robert Sternberg's conceptualization of intelligence views human cognition as a system of interrelated components that interact to allow an individual to adapt to the environment (Sternberg, 2012). Sternberg describes intelligence as internal characteristics of the individual, experiences that the individual encounters in their life, and the individual's use of their personal skills or attributes in order to adapt to and fit in with their environment. He views an individual as intelligent if they integrate and utilize their abilities to succeed within their sociocultural context. It should be noted that Sternberg's model differs significantly from the other three approaches described here in that the triarchic theory is not based on statistical approaches that provide evidence in favor of convergence of cognitive abilities (*g*) or specific and unique cognitive abilities (e.g., CHC theory). Additionally, this model has not contributed to the development of measures of intelligence but can serve as a heuristic when describing a person's intelligence observed in everyday behavior or as assessed by another intelligence test.

Models in Review

Researchers have devoted significant attention toward defining and describing human intelligence. To date, the two most widely utilized models are based on the notion of a unitary construct of general intelligence (*g*) that individuals demonstrate through varying cognitive tasks and the identification of the primary abilities that comprise the major components of intelligence. The Wechsler framework describes subcomponents of general

intelligence in terms of either four or five factors depending upon the evaluative measure being used and the age of the examinee. In contrast, CHC theory proposes that eight unique factors underlie *g* with a sizable amount of statistical evidence in support of this model. Each of these models has directly applied in the development of formal assessment measures. The PASS model describes human cognition via four interrelated processes that enable an individual to process information. Sternberg's triarchic theory differs substantially in that it emphasizes an individual's capacity to adapt to their unique sociocultural environment as a primary indicator of intelligence and as such, performance on formal measures is seen as less important than evidence of success within one's environment. In general, each model has supporters and critics, and theories of human cognition and intelligence continue to develop as a result of scientific inquiry and healthy debate.

Current Intellectual Assessment Measures

There are a very large number of intellectual assessment measures available for use by professionals (see the Buros Mental Measurements Yearbook and Tests in Print) who have obtained relevant training in standardized test administration and interpretation (i.e., psychologists, psychiatrists, physicians). These tests are designed to provide professionals with an accurate assessment of an individual's cognitive functioning across a number of domains (e.g., verbal abilities, nonverbal abilities, working memory, processing speed, cognitive fluency). Most intelligence measures provide the opportunity for both individual domain scores as well as a single intelligence score indicative of overall cognitive ability (FSIQ). It goes without saying that intelligence tests, like any other psychological measure, must demonstrate that they are valid and reliable; have been carefully standardized with comprehensive norms to aid interpretation; and have practical utility for the psychologist, the client, and any other agencies needing such information for decision-making (e.g., courts, school, military).

The following section briefly outlines two of the most commonly used batteries of cognitive intelligence for children and adults: the Wechsler family of tests and the Woodcock–Johnson Test of Cognitive Abilities. As well, a brief overview of other measures suitable for use in assessing cognitive abilities are also noted, although these measures are generally used less frequently than the Wechsler and Woodcock–Johnson tests.

Wechsler Tests

One of the most commonly used battery of intelligence measures are those initially developed by David Wechsler. His collection of tests allow for examining of intelligence from 2:6 to 90:11 years, with separate measures for preschoolers, children and adolescents, and adults. The Wechsler series also includes a brief measure of intelligence, the opportunity to measure nonverbal intelligence in language-limited populations (e.g., English language learners), and additional measures specifically examining memory and achievement.

The WPPSI-IV (Wechsler, 2012) was recently published in North America and provides a standardized measure of intelligence for preschoolers and young children from ages 2 years 6 months to 7 years 7 months. The WPPSI-IV utilizes child-friendly subscales (e.g., bug search, zoo locations) and engaging photos, and may be completed in as little as 30 min. This measure allows for a comprehensive understanding of early intellectual strengths and weaknesses, including verbal, visual-spatial, working memory, fluid reasoning, and processing speed indices (Syeda and Climie, 2014).

The most commonly used measure of intelligence for school-aged children and adolescents is the WISC-IV (Wechsler, 2003), which is now being superseded by the very recently published WISC-V (Wechsler, 2014). The WISC-V assesses the cognitive abilities of children and adolescents ages 6:0 to 16:11 years. Primary indices include verbal comprehension, visual-spatial awareness, fluid reasoning, working memory, and processing speed, as well as an overall FSIQ and various other composite scores such as the General Ability Index (GAI), incorporating verbal and visual abilities only (Prifitera et al., 2008).

The WAIS-IV (Wechsler, 2008) measures cognitive ability in adults ages 16:0 to 90:11 years. In contrast to the WISC-V, the WAIS-IV provides an understanding of cognitive abilities across four domains (verbal comprehension, perceptual reasoning, working memory, and processing speed) and two composite scores (FSIQ and GAI; Climie and Rostad, 2011; Weiss et al., 2010a).

The *Wechsler Abbreviated Scale of Intelligence – 2nd edition* (WASI-II; Wechsler, 2011) is an abbreviated measure of intelligence for individuals ages 6:0 to 90:11 years. It is appropriate for use to gain an accurate understanding of an individual's cognitive abilities but when it is not necessary or feasible to administer a full battery (e.g., WISC-V or WAIS-IV; McCrimmon and Smith, 2013). Administration time for this measure is approximately 30 min for the four-subtest form and 15 min for the two-subtest form. The WASI-II provides an understanding of verbal comprehension, perceptual reasoning, and an overall full scale score for the four-subtest (FSIQ-4) and two-subtest (FSIQ-2) administrations (McCrimmon and Smith, 2013).

Finally, the *Wechsler Nonverbal Scale of Ability* (WNV; Wechsler and Naglieri, 2006) provides a general cognitive ability assessment for individuals aged 4:0 through 21:11 years who have communication or language difficulties. It is intended for individuals who may have limited English language proficiency, developmental delays (e.g., limited language) or disorders (e.g., Autism Spectrum Disorder), deaf or hearing impaired individuals, or those with language-based learning disabilities (Massa and Rivera, 2009). The WNV provides only a full scale IQ score based on the four subtests comprising this measure.

Woodcock–Johnson Test of Cognitive Abilities

Another commonly used cognitive measure is the WJ-III (Woodcock et al., 2001) and the recently published WJ-IV Cognitive (Shrank et al., 2014). The WJ Cognitive measures can be utilized with individuals from preschool (2 years of age) to adults (over 90 years of age) and provides a strong measure of intelligence across the life span (Blackwell, 2001). Following the CHC model, the WJ-IV Cognitive provides

both standard (subtests 1 through 10) and extended (subtests 11–18) batteries, allowing for general (General Intellectual Ability, GIA; Brief Intellectual Ability, BIA; Fluid and Crystallized Composite, G*f*–G*c*) or detailed understanding of cognitive abilities in the following areas: Comprehension-Knowledge (G*c*); Long-Term Retrieval (G*lr*); Visual Processing (G*v*); Auditory Processing (G*a*); Fluid Reasoning (G*f*); Processing Speed (G*s*); Short-Term Working Memory (G*wm*); Perceptual Speed (P); and Number Facility (N). Additionally, Auditory Memory Span (MS) can be ascertained in combination with additional tasks from the WJ-IV Cognitive battery of measures.

Other Measures

Although the Wechsler and Woodcock–Johnson measures are the most frequently used intellectual assessment measures, other often used measures to examine intelligence include:

- *Stanford–Binet Intelligence Scales – 5th edition* (SB5; Roid, 2003) – the SB5 is a well-known measure of intelligence for individuals aged 2–85+ years of age with a rich history dating back to 1916.
- *Kaufman Assessment Battery for Children – 2nd edition* (Kaufman, 2004): the KABC-II is a culturally sensitive measure of ability for children aged 3–18 years of age.
- *Cognitive Assessment System – 2nd edition* (Naglieri et al., 2012b): the CAS2 is used with individuals 5:0 to 18:11 years of age and was developed following the PASS theoretical framework.
- *Differential Ability Scale – 2nd edition* (DAS-II; Elliott, 2006): the DAS-II uses profile analysis to identify cognitive strengths and weaknesses in individuals aged 2:6 through 17:11 years of age.

There are other intelligence tests available. Some are variations of the above but in shorter formats (e.g., WASI-II), while others focus on specific abilities such as the Raven's Progressive Matrices (Raven et al., 2003) or the Naglieri Nonverbal Ability Test (NNAT; Naglieri, 1997). Still other tests are intended for use when language presents a barrier to assessment, such as the WNV (Wechsler and Naglieri, 2006) or the Universal Nonverbal Intelligence Test (UNIT; Bracken and McCallum, 1998). Together, these cognitive assessment measures provide a detailed understanding of individual cognitive intelligence and allow for a reliable and accurate measure of cognitive functioning whether defined more broadly or specifically.

What Do Intelligence Tests Tell Us?

Broadly speaking, intelligence tests allow for the assessment of a person's cognitive functioning for purposes of identifying those who demonstrate average intelligence, intellectual giftedness, delays, or disability. This information may be particularly useful in the identification of intellectually gifted persons and the diagnosis, intervention planning, and remedial program development for children with learning difficulties, adolescents or adults who may require additional supported living arrangements, or persons who have are suffering intellectual decline due to head injury or dementia.

Furthermore, an examination of different score patterns using tests such as the WISC-V or WJ-IV Cog allows for strength- and deficit-based analysis of examinees' cognitive functioning, particularly in relation to distinct cognitive domains. This information may be particularly useful when creating individual learning plans for school-aged children and adolescents, and may allow individuals working with intellectually challenged adults the opportunity to build on their strengths rather than remain limited by their areas of difficulty.

Social and Professional Issues in Cognitive Assessment

As with any type of assessment, a number of social as well as ethical and professional issues must be considered when utilizing intellectual assessment measures. The following section highlights three important issues, including the necessity of appropriate training and supervision before administering cognitive assessment measures, the role of intelligence assessment with special populations (e.g., deaf or hard of hearing, intellectual disability, Autism Spectrum Disorder), and adaptations for use with culturally diverse individuals.

The first issue concerns the necessity of appropriate training and supervision for individuals who administer cognitive assessment measures. The most complex cognitive assessment measures are identified as 'level C' tests, indicating that the test is restricted to use by professionals with expert training, generally including graduate-level training in psychology (usually a doctorate degree, including specific assessment courses and supervised practice in assessment) or other related professional field, and/or registration in a state, provincial, or national organization that is related to these fields. Test publishers require proof of these credentials before an individual is allowed to purchase these measures. This check provides some control over the sale of these protected measures so as to ensure that test integrity is maintained and that only those with appropriate training and expertise in these areas are permitted to access or administer these measures. There are clear concerns with unauthorized individuals accessing these measures, including inappropriate assessment, diagnosis, or interpretation of results, and it is imperative that these assessments are conducted by appropriately trained individuals who maintain and continue to upgrade their knowledge and skills related to best assessment and ethical practices. Psychologists and others who use intelligence tests for assessment and diagnostic purposes must also adhere to the required standards for professional practice as well as the code of ethics required of them as part of their credentialing.

Second, the role of assessment in unique populations has continued to gain attention over the last few decades stemming from the earlier court challenges in the United States from some 40 years ago. Specifically, the purpose for which intelligence tests are used and the validity of these assessment measures with individuals with special learning and psychological needs has been questioned, leading to a greater emphasis on appropriate and adaptive testing measures. For example, the use of verbally loaded cognitive assessments with

language-limited individuals is clearly problematic. Individuals may present with language difficulties for a number of reasons (e.g., lack of English language knowledge, language disorder, Autism Spectrum Disorder) but may otherwise have intact cognitive abilities. As such, it is important to provide these individuals with an opportunity to demonstrate their intellectual abilities without a reliance on language that could certainly mask important abilities and result in incorrect and misleading conclusions. The WNV (Wechsler and Naglieri, 2006) provides some opportunity to measure cognitive abilities through nonverbal means. As well, other small test modifications may be necessary to ensure that all examinees receive a fair assessment. These modifications may include additional breaks between subtests (for individuals unable to concentrate for long periods of time), removal of fine motor-based subtests (for individuals with motor difficulties, such as cerebral palsy), or beginning with easier test questions for cognitively challenged individuals. These minor modifications may not affect the overall validity of the test and may provide a more accurate understanding of individual skills. A psychologist may also use a more process-oriented approach (e.g., WISC-IV Integrated; Wechsler et al., 2004) or different methods of assessing intelligence, such as dynamic assessment described by Feuerstein et al. (1979, 2002). Of course, it is key to remember that the tests themselves do not make 'decisions' about an individual, psychologists do! Thus, they must be extensively trained to understand and interpret the information gleaned from intelligence tests and other sources of information (e.g., observation, clinical history) in relation to the scores obtained from tests.

Third, the necessity of incorporating a social and cross-cultural understanding into cognitive assessment measures has gained a greater focus (Hambleton et al., 2004; Weiss et al., 2010b). Given the diverse nature of Canadian and American populations but also the very fact that most countries are becoming increasingly multicultural, the consideration of cultural implications in assessment is imperative to ensure that bias does not enter the assessment picture. Bias in assessment can occur when individuals score differently on questions or test measures as a result of individual circumstances and not as a result of a basic underlying trait or ability (van de Vijver and Tanzer, 2004). For example, asking a child 'What is the capital of Kentucky?' may yield a very different rate of accuracy in the United States compared to responses from African or European children. Indeed, even within the United States, accuracy on this question may vary based on individual geographic location (e.g., living in Kentucky versus living in Idaho) or the amount of focus on geographical capital cities within an individual classroom. Although this example is only one illustration of potential bias, on a broader scale, it is important to consider the impact of tests developed and normed in one country being used to assess an immigrant population who may not have the language capabilities or the background information to adequately demonstrate their knowledge and competencies reflective of their underlying intelligence.

Although not exhaustive, this section has noted some of the more significant concerns that must be accounted for in intellectual assessment. Together, these issues highlight some of the considerations necessary for using intellectual assessment measures with unique and/or specialized populations.

Conclusions

Overall, this article has provided a general summary of intelligence and highlighted both historical and conceptual frameworks. A description of the most commonly used cognitive assessment measures is included. Finally, some important social and professional issues are discussed with an emphasis on the ethical use of these measures. Together, it is clear that intelligence and its measurement have evolved over time and should continue to do so as our understanding of cognitive development expands.

Abstract

Scientific inquiries into the nature of intelligence have journeyed for more than a century and have yielded a broad collection of theoretical conceptions and measurements. This article seeks to provide an overview of research on intelligence. Central theoretical conceptions and related measurement issues are reviewed along three orientations (i.e., the product-process, the human-ecology, the lifespan developmental) as well as their relative emphases on interactions between these dimensions.

Lasting Debates in Intelligence Research: The Elusive Concept of Intelligence

Given its practical importance in individual lives and societies, the topic of 'intelligence' attracts much attention and debates both among the researchers and the lay persons alike. The research of intelligence has been pursued by psychometricians, cognitive psychologists, and developmental researchers (see Sternberg, 1994 for comprehensive reviews; see also Intelligence: Historical and Conceptual Perspectives). However, not many other terms in psychology are so elusive as 'intelligence' escaping consensual definitions over more than a century of research. Tracking chronologically the reports of three representative forums, each participated by experts in the field, sheds some light on the changing terrain of intelligence research during the twentieth century.

In 1921, a classical symposium convened by the editors of the *Journal of Educational Psychology* was held to discuss three questions: (1) What is intelligence? (2) How can it be best measured? (3) What are the most crucial next steps in research? (Thorndike, 1921). Among the 17 leading researchers who participated, 14 different answers were given! About one-fourth of the participants suggested elementary sensory and cognitive processes (i.e., perception, sensation, and attention) as primary attributes of intelligence. Another one-fourth of the experts thought that physiological mechanisms of the brain should be the determining factors, and there were still others who contented that overt adaptive behavioral responses are the key features of intelligence. Sixty-five years later, a succeeding effort with 27 experts was arranged to address exactly the same questions (Sternberg and Detterman, 1986). However, the degree of lack of consensus remains similar to what was in 1921: experts of the 1986 forum offered two dozen definitions.

Aside from the diverse conceptions among researchers, two popular books also sparked heated debates in the general public. The views range from renouncing the idea of 'measuring' individuals along the continuum of psychometrically defined intelligence (Gould, 1981) to the belief in a general intelligence factor (Herrnstein and Murray, 1994). Reacting to these controversial debates, at the dawn of approaching a new century the Board of Scientific Affairs of the American Psychological Association called for another authoritative report from a dozen experts in the field to discuss the 'knowns and unknowns' of intelligence (see the report in Neisser et al., 1996). Now we are more than a decade into the twenty-first century, a recent comprehensive update by Nisbett et al. (2012) reviews substantial research progress that has been made in the last 15 years regarding important topics like the heritability and modifiability of intelligence, group differences in intelligence, as well as its neurobiological basis. As for concepts about the definition and structure of intelligence, little new theoretical work has been added in the past decade. There remains a need for integrative frameworks to understand the diversities and controversies surrounding theoretical conceptions and the multivariate determinants of individual differences in intelligence.

Some Lasting Trends and an Attempt of Integration

In order to highlight a few continuing trends that are hidden behind the overwhelming diversities, organizers of the 1986 forum compared the main issues raised in their discussions with those that were discussed in 1921 and showed that there were some general agreements across the two efforts (Sternberg and Detterman, 1986). Specifically, conceptions including attributes such as *adaptation to the environment*, *basic cognitive processes*, and *higher-order thinking* (i.e., reasoning, problem-solving, and decision-making) were prominent in both discussions. In addition, the recurring themes of central debates seemed to surround issues about (1) whether intelligence is unitary or manifold, (2) the relative contributions of nature and nurture to individual differences in intelligence, and (3) the relative emphases on the process, content, and product aspects of intelligence.

As an attempt to compile the two dozen different views, an integrative framework (Sternberg and Detterman, 1986) with multiple levels was also proposed in the report of the 1986 forum. At the behavioral level, theoretical conceptions that originated within the psychometric tradition focus on measuring the 'products' of information processing and on identifying the structure(s) of intelligence. These theories could be compared mainly in terms of whether the structure of intelligence is, more or less, considered to be unitary or pluralistic. At the processing level, the theories attempt to integrate psychometrically defined 'products of intelligence' with various concepts of information processing. In this regard, the various conceptions differ in terms of their differential emphases either on elementary cognitive processes or higher-order cognition involving metacognition, planning, and decision-making. At the contextual level, some theories of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.25014-9

intelligence emphasize the dynamics of human–ecology interaction and the concepts of situated intelligence. Another version of the contextualist theories emphasizes the dynamic contexts of lifespan development from birth into old age. These contextualist theories evolved primarily in conjunction with a focus on the nature of intelligence as adaptive capacity.

Still there have been other theories focusing on genetic and neurobiological influences on intelligence, which are not within the purviews of this article. In the following sections, we review and compare main theoretical conceptions of intelligence with respect to their differences along the product-process, the contexts of human-ecology, and the lifespan developmental orientation, as well as their relative emphases on interactions between these dimensions.

Measuring the Products of Intelligence: From Unitary to Pluralistic and Hierarchical Views

Ever since Alfred Binet's success in devising tests to distinguish mentally retarded children from those with behavioral problems, the psychometric approach to quantify individual differences in cognitive competence using standardized intelligence scales (e.g., the Stanford–Binet test or the Wechsler test) played a dominant role in intelligence research. These scales tend to measure scholastic performance with tasks covering broad domains of functions (e.g., memory, analytical reasoning, numerical skills, verbal fluency, and practical knowledge). Thus, overall the sum scales of such tests predict school performance well. Perhaps not surprisingly because of their emphasis on school-related performances, their predictive validity drops when predicting performance outside of the classroom, such as everyday problem-solving, vocational competence (Dixon and Baltes, 1986), or other more expertiselike outcomes of real-world intellectual functioning (Ericsson and Smith, 1991).

With a more general aim to capture a broader spectrum of human cognitive abilities and their interrelations in addition to the applied orientation of predicting academic performance, a number of psychometric theories have been proposed over last century. Scholars such as Burt, Cattell, Guilford, Spearman, and Thurstone were the main proponents. At the methodological level, these theories differ with respect to the type of factor analytic methods they adopt and whether these methods are applied on the empirical-exploratory or theoretical-confirmatory basis (*see* Factor Analysis and Latent Structure Analysis: Confirmatory Factor Analysis; Factor Analysis and Latent Variable Models in Personality Psychology). At the substantive level, they differ in terms of whether they orient more toward the general factor or multidimensional views of intelligence.

Two-Factor Theory

Although subtests of the intelligence scales are often designed to measure specific domains of cognitive performance (like numerical skill and verbal fluency), performances across different tests tend to be positively correlated with each other (i.e., the so-called *positive manifold*). Spearman (1904) first presented a theory of general intelligence which he later expended into what is now known as the two-factor theory. He developed the first statistical model for explaining the positive manifold among task performances. The underlying assumption of this model is that individual differences in a given test can be decomposed into two components. One variance component is common to all other cognitive tasks – a general factor of intelligence (commonly known as *g*), whereas the other component is specific to each task (Spearman, 1927). With this method, Spearman showed with several data sets that *g* accounted for all positive correlations among the test performances (see Jensen, 1998; for a review on *g*). Since then, hundreds of other studies have also found that *g* accounts for rather large portions of the common variance among a broad selection of cognitive tasks.

The Primary Mental Ability Theory

Since the discovery of *g*, a main issue in psychometric intelligence research has been whether the structure of intelligence is unitary with one general common factor or pluralistic with multiple specific factors reflecting domain-specific abilities. Among the first to question the unitary view was Thurstone, who developed multiple factor analytic techniques and conducted studies that included a broad range of paper-and-pencil items found in most other intelligence scales. In these studies, Thurstone (1938), for instance, was able to identify seven distinct factors reflecting spatial, perceptual speed, numerical, verbal, fluency, memory, and reasoning abilities. However, his assumption of these primary mental abilities being completely orthogonal to each other was not empirically supported. Instead, multiple common factor models later proposed by others showed that the positive manifold emerges again at the level of higher-order factors.

The *Gf-Gc* Theory and Related Theories

Building on the multiple primary abilities identified by Thurstone, one influential conceptual model since then has been the *Gf-Gc* theory (Cattell, 1971; Horn, 1982). Based on results from higher-order factor analyses, this theory distinguishes general fluid (*Gf*) abilities reflecting the individual's basic problem-solving, reasoning, learning, and selective attention capabilities from general crystallized (*Gc*) abilities reflecting the acquired knowledge and their utilization. Unlike Thurstone's theory, which assumes independent primary mental abilities, Cattell proposed the ontogenetic *investment theory* to specify a possible mechanism relating *Gf* to *Gc*. He postulated that the culture-, experience-, and knowledge-based crystallized abilities arise, in part, as a result of a process in which the more biology-, maturation- and process-based fluid abilities have been *invested* into suitable learning experiences and contexts as the individual develops. The *Gf* and *Gc* distinction is often compared with Hebb's (1949) differentiation between innate potentials for information processing (Intelligence A) and the acquired level of performance and comprehension (Intelligence B), and Paul B. Baltes' (1987) juxtaposition of the cognitive mechanics and the cognitive pragmatics (see more details in a later section). Besides these two central broad factors, Cattell and Horn were also able to identify several other factors reflecting visual processing ability (*Gv*), short-term memory (*Gsm*), quantitative abilities (*Gq*), associative

storage-retrieval (*Glr*), novel reasoning (*Gr*), and processing speed (*Gs*). These factors have been further verified and captured by comprehensive psychometric test batteries developed by others, such as the Stanford–Binet, Wechsler, and Woodcock–Johnson batteries.

The Structure of Intellect Model

Moving even further away from the unitary pole of *g* and working toward better delineating the process and product aspects of intelligence, Guilford (1967) proposed the structure of intellect (SOI) model, which specifies the (1) operation, (2) content, and (3) product components of intellectual abilities. The component of mental operation contains five general intellectual processes: cognitive, memory, divergent production, convergent production, and evaluation. The content component encompasses four broad areas (i.e., figural, symbolic, semantic, and behavioral) of information to which operations are applied. The product component entails six possible results (i.e., units, classes, relations, systems' transformations, and implications) of applying particular operations in particular contents. Applying factor analytic techniques in a confirmatory manner to test this model deductively, Guilford expected the structure of intellect to result in 120 single independent factors of different operation × content × product ($5 \times 4 \times 6$) combinations. However, in later modifications he acknowledged that the first-order factors could be correlated, therefore giving rise to multiple higher-order factors, but he still denied the existence of a general factor (Guilford, 1982). On the one hand, the strength of the SOI theory is its more specific and refined definition of ability structure across dimensions capturing three distinct aspects of information processing. On the other hand, the main critiques of the model targeted at the fact that this model was derived through the use of a certain factor rotation technique (i.e., the procrustean rotation) which later was criticized to be subjective to confirmatory bias and lacking empirical support for most of the factors specified.

Another theoretical model akin to Guilford's faceted conceptualization is the Berlin model of intelligence structure (BIS) by Jäger (1984). This model cross-classifies each cognitive test with respect to an (1) operation and a (2) content facet. Operation is further categorized into four ability groups (reasoning, memory, creativity, and speed), whereas content is divided into three groups (figural, numerical, and verbal). Conceptually, the 12 operation × content (4×3) combinations taken as a whole represents general intelligence. However, by factoring groups of variables that are homogeneous within one of the two facets but are heterogeneous in the other facet, one can either extract the four operational or the three content factors. Specified as such, methodologically this model implies that any given mental ability is a linear combination of the two factors, and conceptually it simultaneously specifies a mental ability with a process and a content aspect.

The Three-Stratum Theory

Reanalyzing 477 available covariance matrices of cognitive ability tasks, Carroll (1993) integrated the findings from the different theoretical schools into a hierarchical structure with three stratums. At the lowest stratum, more than 60 narrow first-order abilities could be found. Given these narrow abilities are positively correlated with each other to varying degrees, a second stratum of broad abilities, which closely resemble the primary mental abilities identified by Thurstone and by Cattell and Horn, could also be extracted. At the highest stratum, a general factor of intelligence captures the positive manifold among the broad ability factors at the second level. The hierarchy with all three stratums then describes the overall structure of intelligence. In terms of empirical breadth, this model comprehensively integrates the empirical basis of human cognitive abilities observed at the behavioral level. In terms of theoretical integration, it shows that diverging psychometric views of intelligence can be understood in terms of their differential focus on one of the stratums within the overall structure, selections of indicator tasks defining the lowest level of the structure, and adoptions of factor-analytical techniques.

Regarding the behavioral psychometric approach to intelligence research as a whole, a key issue that remains is whether factors derived by factor analysis are entities with causal status or organizational concepts capturing a system of the products of intelligence. Defining the structure of intelligence with multiple levels, going from multiple low-level specific abilities to intermediate broad abilities, and, finally, to a general factor at the highest level, has advantages for relating to other theoretical conceptions. Various conceptual connections from psychometric measures of intelligence to other theoretical conceptions that either emphasize inward cross-level integration with information-processing mechanisms and their biological correlates, outward integration with real-world everyday knowledge and problem-solving skills, or lifespan developmental integration can be more easily drawn.

Integrating Psychometric Intelligence with Cognitive Processes

Starting from late 1970s, there has been a development toward specifying the processing aspects of intelligence in hierarchical models within the psychometric tradition and the development of investigating information-processing mechanisms in cognitive science in general. With the parallel developments in both fields, researchers of intelligence started to integrate information-processing concepts into the theoretical conceptions of intelligence. Some theories focus on integrating the measurement and explanation of intelligence by looking inwardly and downwardly within the individual for elementary information-processing correlates (e.g., processing speed and working memory) of intellectual abilities (e.g., Hunt, 1980; Resnick, 1976) and their neurobiological correlates (Eysenck, 1982; see Deary, 2000 for a recent overview). Other theories focus on relating intelligence with aspects of information processing that are more closely related to real-world competence, such as complex reasoning, metacognition, planning, knowledge, vocational skills, and expertise (e.g., Ackerman, 1996; Sternberg, 1985, 1999).

Mental Speed Theory

The notion that information-processing speed may underlie individual differences in intelligence goes back all the way to

Galton, who tried to measure intelligence by simple sensory and reaction time tasks. Researchers dedicated to the mental speed approach have taken up Galton's initial idea to investigate the relation between intelligence and reaction times measured in a broad range of simple elementary cognitive tasks (see Jensen, 1998; Vernon, 1987; for reviews). Performances in these tasks tend to be perceptually based and do not require any semantic or practical knowledge. Thus, it is perhaps no surprise that the correlations between the reaction times measured with such simple tasks and intelligence have proven to be only moderate (i.e., hovering around the so called 0.3 barrier, Hunt, 1980). Proponents of the elementary information-processing theory in general and the mental-speed theory in particular admit that simple reaction time measures are inferior to more complex composite measures derived from mental tests for the measurement and prediction of intelligence. However, they argued that the moderate but consistent correlations between measures derived from simple elementary information-processing tasks and performance on mental tests may be important for unraveling the information-processing aspects of intelligence. Variations in the observed correlations across studies and their theoretical interpretations have been the issues of much discussion. The interpretations range from proposing nerve conduction velocity as the basic biological parameter for all cognitive functioning, to several alternative explanations postulating higher-level constructs like attention, motivation, personality factors, or speed-accuracy trade-offs, to be the causes for a spurious relationship between intelligence and mental speed measured with simple decontextualized tasks.

Working Memory Theory

Another aspect of cognitive function that has been deemed as a likely candidate information-processing correlate of intelligence is working memory (Baddeley, 1992). Working memory reflects people's ability to briefly maintain information, while simultaneously carrying out other mental operations on the same or other information. Empirical evidence suggests that tasks requiring greater working memory loads tend to correlate more highly with intelligence. Furthermore, it has also been found that working memory capacity correlates highly with psychometric reasoning (Kane et al., 2005; Kyllonen and Christal, 1990). Taken these findings together, proponents of this theory suggest that working memory might be a better candidate process for explaining fluid intelligence than mental speed (Engle et al., 1999; Süß et al., 2002).

The PPIK Theory

Staying with the general sentiment of relating intelligence with information processing, but orienting more toward issues on knowledge representation in artificial intelligence systems rather than the experimental cognitive approach, Ackerman (1996) proposed an integrative framework characterizing adult intellectual development as complex interactions between cognitive processes, personality traits, broad interest, and knowledge (PPIK) domains. This framework can be seen as a starting point for disentangling the complex relations between the different aspects of intellectual functioning and personality-motivational modulators (Ackerman and Heggestad, 1997). For instance, there is ample evidence indicating that personality traits, such as degrees of openness to experience and typical intellectual engagement, are substantially correlated with crystallized knowledge (von Stumm and Ackerman, 2013), but much less so with fluid ability. Such findings motivate further intelligence research to explore the roles of broad domains of occupational and avocational knowledge in adult intelligence, which has not been captured sufficiently by the traditional assessment of *Gc*.

The Triarchic Theory

Sternberg's triarchic theory of intelligence (1985) is another example of an integrative theory that seeks to combine traditional psychometric approach with information-processing perspectives at the level of higher-order cognition, rather than elementary cognitive processes. Three different kind of information-processing components are distinguished in the triarchic theory. *Metacognitive components* are higher-order control processes used for executive planning, monitoring, and evaluating task performance. *Performance components* are lower-order processes that deal with the execution of a task itself. For instance, in an inductive reasoning task, the performance components may involve encoding the test word pairs, comparing the word pairs, and retrieve from memory information about the test items. The *knowledge-acquisition components* are processes involved in learning, retaining, and integrating new information with old experiences. Sternberg (1999) had extended his original theory to encompass a broader spectrum of issues regarding successful everyday real-world competence. For instance, in everyday context, successful intelligent individuals are likely to invoke metacognitive higher-order regulatory thought processes to discern their own strengths and weaknesses, and device strategies to maximize their strengths but compensate for their weaknesses. While this theory is more integrative and ecologically valid in nature, details of many components of the theory await further specification and empirical testing.

Bioecological and Lifespan Theories of Intellectual Development

Traditionally, developmentalists have also been among the researchers of intelligence. Piaget, the pioneer of modern developmental psychology (*see* Piaget's Theory of Cognitive Development), studied the development of mental processes through which knowledge is constructed during ontogenesis (Chapman, 1988). The Piagetian view of intelligence focuses more on the processes of intelligence, rather on the products of intelligence and the individual differences therein. Specifically, central to Piaget's theory of intelligence (1960) is the view that adaptive behavior and knowledge are constructed through an intimate interplay between the child and the environment. Intellectual development results from the child generalizing her current behavior and knowledge to new situations (assimilation) and also adaptively modifying his or her current behavior

and knowledge through new experiences (accommodation). Influenced by Piaget's conceptions, two main variants of later theories of intellectual development share common endorsements of gene-environment (or biology-culture) coconstructivist and contextualist views.

The Bioecological Theory

With its main focus on understanding the complex interactions between biology and ecology in shaping child development, the bioecological theory (Bronfenbrenner and Ceci, 1994) proposes that aside from genetic effects individual differences in intellectual functioning are the result of variations in the bioecological interactions a child experiences during development. The theory has three main tenets. First, there are multiple innate abilities, as opposed to a single ability. Second, innate abilities serve as a range of possibilities that may develop, or fail to develop depending on their interactions with mechanisms and processes in the proximal developmental contexts (e.g., such as parent–child interactions and schooling). Third, motivation plays important modulatory roles in determining how much the environmental context aids the actualization of the individual's innate potential for intellectual development. The notion that interests and motivational factors play a role in intellectual development has also recently been considered in the PPIK theory (see above).

The Dual-Process Theory of Lifespan Cognitive Development

While also being coconstructive and contextual in nature, the dual-process theory of lifespan cognitive development focuses on understanding the biology–cultural interplay in the gains and losses of intellectual development across the lifespan from early childhood into old age (e.g., Paul B. Baltes et al., 1999). The lifespan developmental theory has been developed by combining both the psychometric and lifespan developmental approaches.

Combining Hebb's Intelligence A and Intelligence B distinction (see above) and the Cattell–Horn *Gf-Gc* framework with perspectives from cognitive and evolutionary psychology, the dual-process theory of lifespan cognitive development highlights two distinct but interacting aspects of intellectual functioning: the biologically driven cognitive mechanics of basic information processing, and the contextually driven cognitive pragmatics of culture-based bodies of acquired factual, procedural, and profession-related skills and knowledge. Furthermore, with an emphasis on the dynamic of lifespan development, the dual-process theory also focuses on how these two aspects of intellectual functioning interact with each other, develop, maintain, and decline throughout the lifespan. In line with Cattell's investment theory, the dual-process theory proposes differential lifespan trajectories for the cognitive mechanics and pragmatics. The biologically driven cognitive mechanics display an early growth pattern which is then invested into the acquisition of pragmatic skills and knowledge. While most abilities of the cognitive mechanics start to decline in midlife, the efficacy of culture-, experience-, and expertise-based pragmatics remain, well into old age; or, as suggested by Ackerman (1996), lifelong occupational and avocational knowledge could still be maintained or even increase up to late adulthood. However, in old age the role of biology-based cognitive mechanics in regulating the culture-based cognitive pragmatics increases. The lifespan developmental orientation to intelligence research provides the insight that the structure and dimensionality of intelligence are themselves subject to change as the individual's brain resources mature during child development, remain stable in adulthood, and decline in old age. The differentiation-dedifferentation hypothesis by Baltes et al. (1980) postulated that intellectual abilities are rather undifferentiated in childhood, undergo differentiation during maturation, leading to a multifaceted intelligence structure that remain mostly stable in adulthood; and become undifferentiated again during aging. In a lifespan sample covering the age range from 7 to 89 years, Li et al. (2004) indeed found that the dimensionality of the manifold of intellectual abilities and their component processes expands from childhood to adulthood and constricts during the course of aging.

Challenges to the Theoretical Status of Ability Factors

More than a century of research on the structure of intelligence and on correlates of cognitive ability factors in terms of their antecedents at the information-processing and biological level as well as consequences at the level of real-world outcomes was based on the investigation of differences between individuals. Yet, the scientific goal of better understanding intelligent behavior targets behaviors like problem-solving, reasoning, and learning at the level of processes within single individuals. In a seminal article, Borsboom et al. (2003) have argued that the factor-analytic approach to the structure of intelligence implies an interpretation of the latent ability factors as real entities that cause the overt behavior of performance on test items (rather than just being descriptive constructions). As the usual approach of measuring people only once on a set of test items provides no basis for demonstrating such causality at this level of individual persons, the huge available empirical evidence from hundreds of individual differences studies is actually mute about the structure and the processes underlying intelligent behavior of individuals. What is therefore required in addition to the well-established research on the structure of between-person differences is research on the structure of within-person fluctuations and changes in cognitive performance (cf Molenaar, 2004).

Borsboom et al.'s challenge of the explanatory value of ability factors as common causes of performance on different cognitive tasks resonates well with recent theoretical proposals that question the need of a general factor *g* to explain the positive manifold among cognitive tasks. van der Maas et al. (2006) proposed that this positive manifold could be explained well by mutualism, that is, beneficial interactions between different cognitive processes during development. Similarly, Dickens (2007) put forward the idea that higher levels on one or some of relatively independent skills could denote advantages for individual people, putting them into more favourable environments, which in turn foster the development of other skills, ultimately leading to a pattern of

positive correlations among performances that gives rise to a g factor. Similarly, Kan et al. (2011) recently argued that there is no need for a separate ability of *Gc* as the cause of performance on knowledge items and that the fact that different such items tend to load on a common factor should rather be interpreted as the result of the acquisition of knowledge taking place in a structured way, which is determined by, for example, the exposure to information in educational settings.

Concluding Remarks

As reviewed above, there is a continuing effort in intelligence research at evolving its subject matter in terms of which mental representation and phenotypic behavioral expressions of intelligence are part of the theoretical conceptions. A few other themes, although deviating somewhat from the more traditional conventions, have been evolving in parallel with the theoretical conceptions reviewed thus far, and merit acknowledgments. For instance, there have been growing emphases on various forms of expertise, such as professional skills or cognitive skills associated, e.g., with chess, medicine, or computer programming, as part of the core of intelligence (see Ericsson and Lehmann, 1996; Newell and Simon, 1972; for reviews). Other examples are the various lines of research on extending the predominately cognition-oriented conceptions of intelligence to social intelligence, emotional intelligence (e.g., Davies et al., 1998; Ford, 1982; Mayer and Geher, 1996; *see* Emotional Intelligence and Competencies), and other presumably separable intelligences, such as musical, spatial, and interpersonal intelligence (i.e., the Multiple Intelligence Theory, Gardner, 1993).

As it is evident from the debates and controversies since Galton and Binet, it is not fruitful for intelligence research to continue with questions such as: Is intelligence unitary or pluralistic? Is the goal of intelligence research to measure the end product of intellectual functioning and to predict performance, or is it to explain the processes of intelligence? Which plays a greater role in the development of intelligence, nature or nurture? Looking at the terrain of current intelligence research and its related fields, it is probably more fruitful to ask questions that highlight the differential utility of the various conceptions of intelligence in furthering our understanding of the complex dynamic interplay between neurobiology and sociocultural contexts in shaping intellectual development. For instance, given existing data at the different levels, which facets of intelligence maybe more biologically driven and which are more context- and culture-based? Which aspects of intelligence are primarily implemented through elementary information-processing mechanisms and their genetic and neurobiological correlates, which other aspects are open to influences from metacognitive, personality, and motivational factors? Which aspects of intelligence are of more direct relevance to real-world problem-solving? What are some aspects of intelligence that might be culture-invariant, and which other aspects are culture-dependent?

Integrating most of the central conceptions of intelligence developed over the last century reveals that intelligence as a phenomenon has multiple facets and levels, and is dynamic both in terms of information processing and in terms of the varying contexts in which it is expressed during individual ontogeny. Couched within an integrated framework, intelligence may be viewed as biologically implemented information-processing capabilities together with knowledge and expertise giving rise to adaptive behaviors in different domains of functioning that are coconstructed through the interplay between sociocultural contextual influences, and the genetic and neurobiological mechanisms across lifespan development. A growing Zeitgeist is more and more in the orientation of biocultural coconstructivism.

Abstract

Behavioral genetic research has made significant contributions to the understanding of individual differences in cognitive abilities. Hardly any other behavioral dimension or disorder has been studied so extensively in behavioral genetic research as general cognitive ability. Based on the results of this research (mainly family, twin, and adoption studies), the importance of both genetic and environmental influences on human intelligence can be considered very well established. This research has also shown that genes become more important with age, drive stability while not being invariant across development, and drive the correlation among various aspects of cognition. More recent studies have further identified moderators on the heritability of general cognitive ability such as income and socioeconomic status, indicating a genotype–environment interaction (which refers to the genetic control of sensitivity or susceptibility to differences in the environment or, in other words, the environmental control of gene expression). Progress in finding specific gene variants for intelligence has been much slower, and molecular genetic studies have yet to identify variations in specific genes that are firmly associated with intelligence differences (with the exception of variation in the apolipoprotein E (APOE) gene).

One of the most prominent questions in many fields within psychology concerns the origins of observed differences among individuals. In particular, individual differences in human intelligence are in the focus of psychological as well as the public interest given their societal significance. In this article, we will address this research question within the framework of behavioral genetic research designs. Behavioral genetics is the study of the influence of an individual's genetic makeup on his or her behavior and the interaction of genes and environment insofar as they affect behavior (Plomin et al., 2013). Two methodological approaches can be distinguished within behavioral genetics: Quantitative behavioral genetics and molecular genetics.

Quantitative behavioral genetics deals with the contribution of genetic and environmental factors to the etiology of individual differences in any complex human trait. When a single trait is considered, the observed trait variation of the population is decomposed into sources of genetic and environmental variation using genetically informative designs, i.e., twin, adoption, and family designs. Additionally, genetically informative designs allow the investigation of the causes of covariation between two or more traits, as well as the causes of stability and change over time when considering multiple traits or points of measurement.

Molecular genetic research aims at identifying specific genes and gene loci responsible for interindividual differences in behavioral traits. Molecular genetic studies use candidate gene or genome-wide association techniques. Within the former approach, a gene that is polymorphic (i.e., has multiple alleles) is selected based on prior findings or on the known function of a gene's protein and it is tested whether people with different alleles tend to differ in the trait under study. While candidate gene studies are hypothesis driven, genome-wide association studies (GWAS) are hypothesis free as the association between a phenotype and a large number of genetic variants spread across the human genome is investigated. If significant genome-wide associations are identified, it is tested which of these associations are robust and replicable (Deary, 2012).

This article will provide a concise overview of behavioral genetic research results in the study of individual differences in general intelligence, not only with respect to heritability estimates and the current state of research attempting to identify specific genes, but also with a focus on the importance of genes across the life span and the environment.

General Cognitive Ability

Individuals undoubtedly differ from one another in their cognitive abilities, e.g., their verbal, spatial, and reasoning ability as well as their memory ability and processing speed. It is also well understood that these differences are predictive of a large range of important life outcomes such as school performance, academic and job success, as well as health, illness, and death (Deary, 2012; Gottfredson, 2002). Today, there is a broad consensus that cognitive abilities are hierarchically organized with a general factor of cognitive abilities (often called *g*) at the highest level (Carroll, 1993). The *g*-factor captures the common variance among the first-level (test-specific factors, i.e., the specific cognitive test that is applied) and second-level factors (broad domains of cognitive functioning, e.g., verbal ability, numeric ability, spatial ability, memory), and it has been shown in many studies that *g* accounts for around 40–50% of the variance in different psychometric intelligence tests (Jensen, 1998). In fact, the *g*-factor is one of the most replicated findings in psychology and its denotation stretches back to 1904 when Charles Spearman described the phenomenon of positively correlated cognitive test scores for the first time and interpreted this as a reflection of a single general factor of intelligence. Although there is still some ongoing debate about the exact organization and labeling of the broad domains of cognitive abilities and how they relate to *g*, it is undisputed that it is primarily *g* that captures the predictive validity as well as most of the variance in the trait intelligence (Gottfredson, 2002). Furthermore, individual differences in cognitive abilities are highly stable across the life span. A unique study conducted by Deary and colleagues was based on data of the Scottish Mental Survey and demonstrated a stability of $r_{tt} = 0.66$ between 11 and 79 years of age in a sample of more than 500 participants who

took intelligence tests in 1932 and, again, in the year 2000 (Deary et al., 2004). Indeed, most of the genetic research to date has also focused on a higher substrate of mental abilities (e.g., IQ scores).

Genetic Influence on *g*: Quantitative Behavioral Genetic Research

In quantitative behavioral genetics, nature (genetics) and nurture (environment) are studied simultaneously as two sources of interindividual differences. Differences in human traits (e.g., general cognitive ability) are attributed to relative proportions of genetic differences and differences in environmental factors that contribute to the phenotypic differences under study. Genetic variance comprises *additive* and *nonadditive* influences. The basic idea of additive genetic variance is that many genes of small effect 'add up' across alleles or loci to influence a trait (Bouchard, 2009). On the other hand, nonadditive genetic variance refers to the genetic effects that depend on interaction across alleles (i.e., dominance) or loci (i.e., epistasis). As environmental sources of variance, a distinction is made between environmental variance that specifiable groups of individuals (i.e., siblings reared together) have in common and therefore contributes to their similarity (such as socioeconomic status (SES), parenting style, family climate) and environmental variance that acts to make them different from each other (such as peers, illness, preferential treatment by one parent) (Bouchard, 2009). The former environmental effects are called *shared* or *common environmental* variance; the latter are called *nonshared* or *specific environmental* variance, which also includes measurement error. Finally, *heritability* is defined as the proportion of (measurable) variability in a phenotype that is 'accounted for' (in the usual regression sense) by variation in genotype (Nisbett et al., 2012). In view of this definition of heritability as the ratio of two variances (i.e., the genetic variance over the total phenotypic variance), it becomes clear that the heritability of a trait always depends on the relative variances of both, genotype and environment. As such, heritability is a descriptive (group) statistic that is solely applicable to the population being studied and not to the phenotype of one single person. That is, depending on the relative variability of the genetic makeup and the environment in a specific population, heritability can theoretically take any value for any trait. Based on this premise, it is apparent that the idea of a 'true' heritability for the heritability of intelligence is nonsensical.

It is also important to address a common misunderstanding regarding the interpretation of quantitative behavioral genetic results. The definition of heritability as a group statistic that is not applicable to the individual implies that chances in environmental conditions (e.g., education practice) can lead to a change in the heritability of a trait. Moreover, high heritability scores do not imply that individual intelligence scores are immutable in terms of interventions.

The relative influence of genes and environment on *g* has been studied since the beginning of psychology. In 1865, 1 year before the publication of Gregor Mendel's seminal publication on the laws of heredity, Francis Galton published two papers on the inheritance of high intelligence and other abilities, later expanded into the highly recognized book *Hereditary Genius: An Inquiry into Its Laws and Consequences* (originally published in 1869; Galton, 1869). Galton ascertained that high intelligence runs in families, an observation that lead him to conclude that high abilities are natural in origin and are inherited from one generation to another. This assumption has been confirmed by dozens of classic and recent twin, family, and adoption studies including data from a total of more than 40 000 pairs of siblings, twins, parent–offspring, and adoptive families from various countries. A first systematic review of genetic research on *g* was published in 1963 by Erlenmeyer-Kimling and Jarvik, and showed converging evidence for genetic influence. Since those early years of genetic studies, both our understanding of the underlying biological mechanism as well as the statistical methodologies have grown tremendously, but yet nothing has refuted the original conclusion that cognitive abilities are under strong genetic influence, with estimates of the effect size of genetic factors ranging from 30 to 80% with an average of 50% explained variance (e.g., see review by Nisbett et al., 2012). Moreover, results from multivariate genetic analyses, which can be used to study the causes of the covariation of specific cognitive abilities, indicate a significant overlap of genetic influences on diverse cognitive facets. This has led to the conclusion that it may be the same genetic factors that largely influence different abilities, or, in other words, that the hierarchical model of cognitive abilities is probably largely genetic in origin (Deary, 2012; Plomin et al., 2013).

At this point, it is important to mention several other factors, which need to be considered when evaluating the heritability of general cognitive abilities. One is a phenomenon that is known as *assortative mating*, which refers to nonrandom mating. With regard to intelligence, brighter women tend to mate with brighter men, reflected by a spouse correlation of about 0.40 for *g* (Plomin et al., 2013). Assortative mating results in offspring that differ more from the average than would be expected under random conditions. This way, assortative mating increases the genetic variability in a population (Plomin et al., 2013). Assortative mating also affects estimates of heritability as it increases the resemblance of first-degree relatives. In twin studies, e.g., this may result in an underestimation of the heritability of a trait because it inflates the similarity of dizygotic (DZ, 'fraternal') twins who are first-degree relatives, but not the similarity of monozygotic (MZ, 'identical') twins who share all of their segregating genes. Consequently, if assortative mating is present for a trait, the difference between MZs and DZs is smaller than under random conditions, diminishing heritability estimates, which are based on these differences.

Another issue concerns the fact that based on the majority of studies so far, most of the genetic variance in *g* appears to be additive. However, there is some evidence that nonadditive genetic effects may also be relevant, yet may well have been neglected in the classical twin design. This is because the classical twin design relies on the assumption of random mating and has to assume that either nonadditive genetic factors *or* shared environmental influences are absent since the two cannot be estimated simultaneously (see Neale and Maes, 2004 or Plomin et al., 2013). In the presence of both assortative mating and nonadditive genetic effects, the pattern of MZ and

DZ twin similarities may wrongly be interpreted as additive genetic effects, thus deflating estimates of nonadditive genetic effects. A recent study by Vinkhuyzen and colleagues utilized an *Extended Twin Family Design*. Such more complex behavioral genetic designs allow the simultaneous estimation of nonadditive genetic effects and shared environmental effects while additionally controlling for effects of assortative mating and cultural transmission (see e.g., Keller et al., 2009; Medland and Keller, 2009). This study revealed that the variance of general cognitive ability in adulthood was not only due to additive genetic factors (44%) but also to nonadditive genetic factors (27%). The remaining variance was explained by nonshared environmental factors and variants of assortative mating (11%) (Vinkhuyzen et al., 2012).

Despite those restrictions, the overall picture of behavioral genetic results for *g* appears to be rather consistent: About half of the variance is due to genetic factors, which are predominantly additive in nature. Shared environmental effects explain about 25% of the remaining variance and 25% are due to nonshared environmental effects and measurement error. It should be noted, however, that these average results are largely based on children data (Plomin et al., 2013). Furthermore, heritability estimates have been shown to vary notably across the life span as well as across different environmental conditions (e.g., socioeconomic classes).

Genetic Influence on *g* Increases during Development

It is now well established that the heritability of intelligence is not the same at different ages. Heritability estimates increase across the life span, from 0% at 3 months of age (Wilson, 1983) to about 30% at 2–6 years of age (Spinath et al., 2003) to 50% in early adulthood (e.g., Haworth et al., 2010) and to as much as 70–80% in mid to late adulthood (e.g., Reynolds et al., 2005). However, there is also some evidence for a decreasing heritability in the very old age. A review of twin studies in the elderly estimated the heritability of *g* at about 60% at 82 years of age (Lee et al., 2010), which suggests that environmental factors, such as physical health may become more important toward the end of the life span (Segal and Johnson, 2009).

Just as the genetic influence on intelligence increases across the life span, environmental influences decrease, and, interestingly, shift with regard to how they operate: While shared environmental influences appear to be more important early in life and in childhood, nonshared environmental influences become more important later in life. For example, a recent study by Haworth et al. (2010) combined raw IQ data from six large twin studies from the United States, the United Kingdom, the Netherlands, and Australia. This study provided strong statistical power and confirmed a rise in heritability from childhood (mean age of 9; 41%), to adolescence (mean age of 12; 55%), to young adulthood (mean age of 17; 66%). The nonshared environmental variance remained stable from childhood (26%) to adolescence (27%) and then dropped slightly in young adulthood (18%). The reverse trend was observed for shared environmental variance, which declined rapidly from childhood (33%) to adolescence (18%) and then remained stable at this level until young adulthood (16%).

Two likely influences have been put forward to explain this occurring pattern. First, small genetic effects present in early childhood might multiply over time, leading to larger phenotypic effects (Segal and Johnson, 2009). This explanation seems especially reasonable given the increasing complexity of cognitive tasks with age and the fact that significant structural brain developments occur from early to middle childhood (Haworth et al., 2010). Second, heritability rises and shared environmental influence declines as individuals play an increasingly more active role in selecting and shaping their environments according to their genetic makeup (Haworth et al., 2010; Johnson et al., 2011), which may also reflect active gene–environment correlation (the concept of a genetic influence on the exposure to the environment or, in other words, the fact that certain genotypes are selectively found in certain environments; Plomin et al., 2013). What is also found is that MZ twin similarity remains relatively stable over time, whereas DZ twin similarity rather tends to decrease. This could also be viewed as a stronger response to environmentally triggered change from individuals who share fewer genes (Bergen et al., 2007).

In addition to considering the variation in the heritability of *g* at different ages, longitudinal behavioral genetic studies have investigated the extent to which genetic and environmental influences contribute to stability and change in *g* (see e.g., Neale and Maes, 2004, for an introduction to multivariate behavioral genetic analyses). *Genetic change* in this respect means that genetic effects at one age differ from genetic effects at another age (Plomin et al., 2013). A genetic contribution to change is expected when intraindividual differences in *g* scores from age to age show genetic influence. Various behavioral genetic studies have been conducted to address this issue with the overall conclusion that the vast majority of genetic effects on *g* contribute to continuity from age to age rather than to change (e.g., Bartels et al., 2002). However, particularly in childhood, genetic factors also account for part of the change. In the same vein, a recent meta-analysis of longitudinal twin and adoption studies aimed at explaining the underlying mechanisms of this developmental increase in heritability (Briley and Tucker-Drob, 2013). Based on a total sample of 11 500 twin and sibling pairs (between 6 months and 18 years of age) the results indicated that the increasing genetic influence on cognitive ability in early childhood is predominantly due to innovative genetic influences. This trend, however, appears to change with age, such that by 8 years of age, the increasing heritability can largely be explained by amplified genetic influences (i.e., genetic influences on cognition are transmitted over time; Briley and Tucker-Drob, 2013). Shared environmental influences, on the other hand, appear to contribute solely to continuity from infancy to middle childhood, and nonshared environmental effects largely contribute to change in *g* across the life span (Bartels et al., 2002; Bishop et al., 2003).

Genetic Influence on *g* Appears to Differ across the Range of Socioeconomic Classes

Over the past 15 years, there is increasing interest in gene–environment interactions, i.e., whether heritability is moderated by an environmental variable such as social class, not least due to rapid methodological advances.

One of the first studies that received extensive attention was based on data from the National Longitudinal Study of

Adolescent Health. Rowe and colleagues showed that the variance in a vocabulary test was explained to different degrees by genetics and environmental influences, depending on mothers' educational level: whereas shared environmental influences accounted for most of the variance in families with poorly educated mothers, genes explained a vast amount of the variance in families with well-educated mothers (Rowe et al., 1999). In a sample of 229 pairs of twins (7 years of age) from the National Collaborative Perinatal Project, a study that is representative in terms of SES (see Nisbett et al., 2012), Turkheimer et al. (2003) examined whether the heritability of intelligence was moderated by environmental factors, i.e., the socioeconomic class. They found a large and statistically significant gene–environment interaction. At the lowest levels of SES, shared environment explained almost entirely the variation in intelligence with practically no genetic effects. By contrast, at the highest SES level, almost all of the variance was explained by genes, and almost none was accounted for by shared environmental effects. In a longitudinal study with children assessed with cognitive tests for the first time at 10 months and again at 2 years of age, there was no variation in the heritability at any level of SES initially. At 2 years of age, significant genetic variance emerged, though only at higher levels of SES (around 5% in low-SES families and 50% in high-SES families; Tucker-Drob et al., 2011). The most recent findings for children are based on data from 2-, 3-, 4-, 7-, 9-, 10-, 12-, and 14-year-old twins from the Twins Early Development Study (Hanscombe et al., 2012). The authors of this study also come to the conclusion that in low-SES families the variance of shared environmental influences is more diverse than in high-SES families, with the effect that the relative importance of genetic effects is smaller in low-SES families.

The case of genetic and environmental interactions with SES after childhood is far less clear. Harden et al. (2007), for instance, found support for a comparable trend to the childhood findings, although the SES variance in their sample of 839 pairs of 17-year-old twins was rather low. Grant et al. (2010), on the contrary, found no evidence for a moderating effect of SES in a study of 5955 male twins of 19 and 20 years of age. In an older sample of adults (36–65 years of age) also no evidence for an interaction emerged (van der Sluis et al., 2008). Based on data from 1702 adult twins (24–84 years of age), Bates and colleagues reported not only that higher SES was associated with higher mean intelligence scores but also that the total phenotypic variance in intelligence was higher in the high SES groups. The observed mean difference between the low versus high SES groups was accompanied by an absolute increase in the genetic variance whereas environmental influences were constant across the range of SES (Bates et al., 2013). From these results the authors conclude that, rather than setting lower and upper bounds on intelligence, genes may multiply environmental inputs that support intellectual growth, and thus triggering the ability to profit from environmental opportunities.

In their comprehensive review of the empirical evidence for differential heritability along the SES continuum, Nisbett et al. (2012) concluded "that the heritability of cognitive ability is attenuated among impoverished children and young adults in the United States" (p. 133) but that it is not possible to generalize this result to other countries due to the mixed results and that it is also not proofed yet whether the effect persists into adulthood. It has been suspected that these differing results among studies could be related to a cultural effect (i.e., smaller socioeconomic differences in cognitive abilities in Europe compared to the United States) and that the case of gene–environment interaction in adulthood is not as clear as in childhood due to a lack of shared environmental components overall, which make it generally difficult to detect significant interactions (Bates et al., 2013; Nisbett et al., 2012). It should also be recognized that large sample sizes are required to detect interactions (van der Sluis et al., 2012) and that an underrepresentation of low-SES families in behavioral genetic studies can cause problems for estimating the heritability of cognitive abilities (see Nisbett et al., 2012).

Genetic Influence on *g*: Molecular Genetic Studies

The quest for genes that influence intelligence has gone on for almost two decades now and many believe that the identification of specific genes will have a great impact on our understanding of the biological and neurophysiological pathways between genes and observed behavior. Advances in molecular biology and genetics have included techniques that make it possible to search the entire genome for genetic variants that may be related to psychological traits. Within the human species, we share over 99.9% of our genetic material. Still, given the size of the human genome, this leaves room for over 3 million expected genetic differences between any two unrelated individuals. These differences are called 'polymorphisms' (when they are found in more than 1% of the population). Some of these variations get translated directly into proteins that control the production of observable individual differences, such as differences in eye color, blood type, and disease susceptibility. Most variations, however, occur in sections of the DNA called 'introns,' and do not code directly for proteins, though they may have regulatory effects on other DNA segments that do. The effects of these polymorphisms on an organism's appearance or function are generally unknown, but the polymorphisms themselves are detectable at the DNA level and can be used as markers. Examples of polymorphisms include single-nucleotide polymorphisms (SNPs), in which a single nucleotide base is substituted for another at a single location in DNA. They also include 'variable number of tandem repeats,' or certain sequences of nucleotides that are repeated within a gene, but the number of repeats vary across individuals. And they include insertion/deletion polymorphisms, in which a sequence of nucleotides is present in one variant, but absent in another.

Quantitative genetic studies can provide a starting point for molecular genetic research insofar as the former type of study can indicate under what circumstances genetic influences make important contributions to the variation between individuals. For complex human traits, such as intelligence, it is reasonable to presume that they are influenced by many genes, each of which has only a relatively small effect. These genes are called quantitative trait loci (QTL), indicating that they are part of a multiple-gene system that contributes to the expression of a trait or disorder. There are two major research strategies within molecular genetics: linkage analysis and association

analysis. Traditional linkage analysis is a technique that detects associations between DNA markers and traits with the aim of mapping genes to chromosomes or to specific regions of chromosomes (see Plomin et al., 2013, for a review). Linkage analysis of large pedigrees has been effective for locating genes for single-gene disorders. For quantitative traits that involve several, up to many, genes of small effect size, however, traditional linkage analysis is not powerful enough. Association analysis in general directly investigates the correlation between a particular allele and a phenotypic trait. Association is typically more powerful than linkage analysis because allelic association has the potential to detect QTLs of small effect sizes. Association has therefore become the method of choice for many researchers over the past decade (Plomin et al., 2013). Within this approach, three different strategies can be distinguished: candidate gene studies, GWAS and genome-wide complex trait analysis (GCTA).

Candidate Gene Studies

Molecular genetics has given us considerable knowledge about many genes that produce specific proteins. Sometimes this knowledge can be used to develop ideas about genes that may be good candidates for involvement in the expression of a trait, because we also have some molecular understanding that their protein products are involved in the trait. Studies that explore this are known as 'candidate genetic association studies.' They compare frequencies of select DNA markers for groups such as individuals with a disorder (cases) versus controls or low-scoring versus high-scoring individuals on a quantitative trait (Sham et al., 2000). If association is present, a particular polymorphism or combination of polymorphisms will be seen more often in individuals carrying the trait than would be expected if it were to occur by chance. The weakness of such studies is that an association can only be detected if the genetic marker is itself the functional gene (direct association) or very close to it (indirect association or linkage disequilibrium). The candidate gene approach therefore requires strong hypotheses as to which genes are good candidates, and we often lack this knowledge (Plomin et al., 2013), since individual differences in complex traits very likely involve the influence of many genes of small effect, any single one of which may not be sufficient or necessary to associate reliably with the trait. To this date, candidate gene studies of intelligence differences have by and large been disappointing: Either no significant association was found at all or the association was not replicable (see Deary, 2012).

Genome-Wide Association Studies

GWAS have become a possible and affordable strategy to identify genes only recently (Hirschhorn and Daly, 2005) and some researchers in this area believe that it is just a matter of time and statistical power until the first robust results are found this way. Through the use of probes for large numbers of SNPs that require only little DNA, systematic scans of the entire genome (DNA) and of the entire transcriptome (RNA) are feasible. The first major GWAS was a search for type II diabetes variants published in Nature in February 2007. By 2008, nearly 100 loci for as many as 40 common diseases and traits had been identified and replicated in GWAS, many in genes not previously suspected of having a role in the diseases under study, and some in genomic regions containing no known genes (Pearson and Manolio, 2008). Since then, a large number of GWAS have been carried out, focusing on a broad spectrum of phenotypic traits, including intelligence. The GWAS strategy has resulted in the identification of reliable links between SNPs and a variety of phenotypes (Johnson and O'Donnell, 2009), including recent findings for schizophrenia (Ripke et al., 2013). In some research areas, GWAS are now analyzed by consortia (e.g., the Psychiatric Genomics Consortium; https://pgc.unc.edu/index.php) that combine forces by either working with joint data sets from different research groups or by conducting meta-analyses of genome-wide genetic data. However, to this date, GWAS findings for intelligence have been disappointing, a fact that is often referred to as the case of 'missing heritability.' For example, the largest GWAS of intelligence, which included almost 18 000 children, found no genome-wide significant association (Benyamin et al., 2014). The largest effect sizes accounted for 0.2% of the variance in intelligence scores. Another recent GWAS of a sample of 1500 children reported an association that accounted for 0.5% of the variance in intelligence scores (Desrivières et al., 2014), but this association was not present in the former study of 18 000 children (Plomin and Deary, in press). To this day, even GWAS on well-established heritable traits such as human height or weight hardly find replicable genetic associations that account for more than 1% of the population variance. Furthermore, testing 500 000 to 1 million SNPs for association, which has become common, presents an unprecedented potential for false-positive results, leading to new stringency in acceptable levels of statistical significance and requirements for replication of findings (Hunter and Kraft, 2007).

Genome-Wide Complex Trait Analysis

GCTA is a new quantitative genetic method that uses DNA to estimate overall genetic influences in large samples of unrelated individuals (Yang et al., 2011). Like other quantitative genetic designs such as the twin design, GCTA uses genetic similarity to predict phenotypic similarity. However, instead of comparing groups of individuals differing markedly in their genetic similarity (e.g., 100% for MZ twins vs 50% for DZ twins), GCTA uses genetic similarity for each pair of unrelated individuals based on that pair's overall similarity across a large number of SNPs. Each pair's genetic similarity is then used to predict their phenotypic similarity. Currently, GCTA detects only those genetic effects tagged by common SNPs and is also limited to detecting additive genetic effects (Plomin and Deary, in press). For this reason, GCTA heritability estimates are typically lower than heritability estimates from twin studies, and they represent the upper limit for detection of SNP associations in GWAS, which, like GCTA are limited to detecting additive effects of polymorphisms. Recent GCTA heritability estimates for intelligence are about half the heritability estimates from twin studies (Davies et al., 2011) suggesting that common SNPs exist which – taken together – account for a considerable portion of the variance in intelligence scores. However, it is also very likely that the heritability of intelligence is caused by thousands of DNA variants, many of which

are likely to be extremely small. It remains an empirical issue, whether and – if so – when such polymorphisms are found and replicated. Another open issue involves the scientific and practical value of such findings, which – at present – come at a high financial cost.

Intelligence: Historical and Conceptual Perspectives

Robert J Sternberg, Office of Academic Affairs, Oklahoma State University, Stillwater, OK, USA

© 2015 Elsevier Ltd. All rights reserved.
This article is a revision of the previous edition article by E. Hunt, volume 11, pp. 7658–7663, © 2001, Elsevier Ltd.

Abstract

This article presents historical and conceptual perspectives on human intelligence. It opens with a brief account of what intelligence is. Essentially, intelligence is viewed as the ability to implement goal-directed adaptive behavior. Then the article discusses major theories of intelligence. First, it describes implicit theories, or what also are called "folk theories" that laypeople hold regarding the nature of intelligence. Then it discusses in turn psychometric, cognitive, biological, and cognitive-contextual theories of intelligence. Next it covers the development of intelligence. And finally it reviews the measurement of intelligence.

Intelligence is the ability to implement goal-directed adaptive behavior. There have been many and diverse theories attempting to explain how intelligence is structured and how it serves adaptive purposes.

Theories of Intelligence

Implicit Theories

How do psychologists know what intelligence is? One way they find out is to ask people. For example, they might ask experts. In a 1921 symposium on the definition of intelligence, an American psychologist, Lewis M. Terman, emphasized the ability to think abstractly. Another American psychologist, Edward L. Thorndike, emphasized learning and the ability to give good responses to questions. In a similar 1986 symposium, however, psychologists generally agreed on the importance of adaptation to the environment as the key to understanding both what intelligence is and what it does. They also emphasized learning skills and understanding one's own cognitive processes.

In a set of studies, Robert Sternberg and his colleagues asked laypeople in the United States what they thought intelligence was. Three factors emerged from their responses: practical problem solving, verbal ability, and social competence. The conceptions that arise depend, however, on who is asked. In a later comparable set of studies carried out in Taiwan, four factors emerged: cognitive skills, getting along with other people, understanding oneself, knowing when to show one is smart, and knowing when not to show one is smart. In other studies conducted in Kenya, cognitive skills also were emphasized less than in the West, whereas obedience, respect, and understanding people were emphasized more.

Most theories of intelligence are explicit rather than implicit, that is, they are elicited not by asking people what they mean by intelligence, but rather, by having people perform tasks alleged to require intelligence and then analyzing the way people perform. There are several different kinds of explicit theories, especially, psychometric, cognitive, biological, and cognitive-contextual.

Psychometric Theories

Psychometric theories have generally sought to understand the structure of intelligence: What form does it take, and what are its parts, if any? Such theories have generally been based on and tested by the use of data obtained from tests of mental abilities. These tests include items such as vocabulary, completing series of numbers, seeing analogies between words, and visualizing what forms would look like if they were rotated in space.

The first of the major psychometric theories was that of the British psychologist Charles E. Spearman. In a 1904 article, Spearman argued that just two kinds of factors underlie all individual differences in test scores. The first and more important kind of factor Spearman called the "general factor," or *g*. It was said to pervade performance on all tasks requiring intelligence. The second kind of factor was specific to each test. But what, exactly, is *g*? In 1927, Spearman proposed it might be something he labeled "mental energy." Many years later, Arthur Jensen suggested it represents speed of neural conduction.

An American psychologist, Louis Thurstone, suggested instead that seven factors, or "primary mental abilities," pervade test performance: verbal comprehension (knowledge of vocabulary and in reading); verbal fluency (writing and producing words); number (solving simple arithmetical computation and reasoning problems); spatial visualization (mentally visualizing and manipulating objects); inductive reasoning (completing a number series or predicting the future based upon past experience); memory (remembering people's names or faces); and perceptual speed (rapidly proofreading to discover typographical errors in a typed text).

Other psychologists, including Raymond Cattell and John Carroll, suggested that abilities are hierarchical. At the top of the hierarchy is *g*, or general ability. But below *g* in the hierarchy are successive levels of gradually narrowing abilities, ending with Spearman's specific abilities.

Cattell suggested that general ability can be divided into two broad kinds of abilities, fluid and crystallized. Fluid abilities are the reasoning and problem-solving abilities measured by tests such as the analogies, classifications, and series completions. Crystallized abilities can be said to derive from fluid abilities and are viewed as their products, which would include

vocabulary, general information, and knowledge about specific fields. John Horn suggested that crystallized ability more or less increases over the life span, whereas fluid ability increases in the earlier years and decreases in the later ones. Philip Vernon and later Thomas Bouchard and his colleague Wendy Johnson argued instead that the distinction at the second level of the hierarchy is not between fluid and crystallized abilities, but rather between abilities that are verbal in nature and those that are more spatial or mechanical in nature.

Carroll proposed a "three-stratum" model of intelligence, which is considered by some to be the most definitive psychometric model of intelligence because it is based upon reanalyses of hundreds of data sets. According to this model, general ability is at the top of a hierarchy of abilities. At the next lower stratum are various broad abilities (including learning and memory processes and the effortless production of many ideas). At the bottom of the hierarchy are many narrow, specific abilities such as spelling ability and reasoning speed.

Cognitive Theories

In a 1957 address to the American Psychological Association, Lee J. Cronbach proposed that psychologists unite the "two disciplines of scientific psychology" – experimental and differential (the study of individual differences). His proposal led to cognitive theories of intelligence, which are derived by experimental means.

Underlying most cognitive approaches to intelligence is the assumption that intelligence comprises a set of mental representations (e.g., propositions, images) of information and a set of mental processes that can operate on the representations. A more intelligent person is assumed to mentally represent information better and also to operate more quickly on these representations than does a less intelligent person.

Earl Hunt, Nancy Frost, and Clifford Lunneborg showed in 1973 that a critical ability underlying verbal intelligence is that of rapidly retrieving lexical information, such as letter names, from memory. A few years later, Robert Sternberg identified key mental processes alleged to underlie many cognitive tasks, especially ones involving inductive reasoning. They included, among others, encoding stimuli, inferring relations between stimuli, and applying what one has learned. Arthur Jensen used a choice-reaction time apparatus to show that speed of making choices – in his view, a proxy for speed of neuronal conduction – is associated with intelligence.

Ian Deary and his colleagues have sought to understand intelligence through the study of inspection time. They have found that more intelligent individuals can discriminate the lengths of the lines with lesser stimulus duration (inspection) times than can less intelligent individuals.

Two leaders in the field of cognitive psychology, Allen Newell and Herbert A. Simon, used computers to model intelligence. The underlying idea is that computers can, in some sense, show a kind of intelligence similar to that shown by humans.

In the late 1950s and early 1960s they worked with a computer expert, Clifford Shaw, to construct a computer model of human problem-solving. Called the General Problem Solver, it could solve a wide range of fairly structured problems, such as logical proofs and mathematical word problems. In 1972, Newell and Simon proposed a general theory of problem solving, much of which was implemented on the computer. It involved heuristics such as means-ends analysis, whereby one seeks at each step of problem solving to reduce as much as possible the distance between the solution and where one is in the problem.

Marcel Just and Patricia Carpenter showed that complex intelligence-test items, such as figural matrix problems involving reasoning with geometric shapes, could be solved by a computer program at a level of accuracy comparable to that of human test-takers.

The models described above are serial-processing models, whereby the computer takes steps in sequence. David E. Rumelhart and Jay L. McClelland, proposed what they call "parallel distributed processing" models of the mind. These models postulated that many types of information processing occur at once, rather than just one at a time.

Biological Theories and Research

Biological approaches to intelligence directly examine the brain and its functioning. Intelligence as measured by IQ tests appears to be localized, in part, in the prefrontal cortex (PFC) and across the neocortex. People with higher IQs show higher levels of functioning in the superior parietal lobes, temporal, and occipital cortexes as well as in subcortical regions of the brain, especially the striatum. Integration of functioning in the parietal and frontal lobes appears to be especially important. Several different biological approaches have been used, most comparing biologically based measures to IQ.

Neural Efficiency

Complex patterns of electrical activity in the brain as prompted by specific stimuli correlate with scores on IQ tests. In particular, speed of conduction of neural impulses may correlate with intelligence as measured by IQ tests. Some investigators have suggested that this research supports a view that intelligence is based, at least in part, on neural efficiency.

Additional support for neural efficiency as a measure of intelligence can be found from studies of how the brain metabolizes glucose during mental activities. Haier and his colleagues have found that higher intelligence correlates with reduced levels of glucose metabolism during problem-solving tasks. Furthermore, Haier and colleagues found that cerebral efficiency increases as a result of learning in a relatively complex task involving visuospatial manipulations (for example, in the computer game Tetris). As a result of practice, individuals with higher IQ demonstrate lower cerebral glucose metabolism overall. But they also show more specifically localized metabolism of glucose. In most areas of their brains, persons with higher IQ show less glucose metabolism, but in selected areas of their brains (thought to be important to the task at hand), they show higher levels of glucose metabolism. Thus, people with higher IQ may have learned how to use their brains more efficiently. These results are not consistent throughout the entire literature.

Studies using electroencephalographic (EEG) methods have also noted a pattern of neural efficiency in intelligent individuals. Using EEG methods, Aljoscha Neubauer and colleagues

noted that greatest neural efficiency was observed in the brain areas associated with the individual's greatest ability.

Today, however, event-related potentials (ERPs) are used more widely than EEGs in the study of biological bases of intelligence. Research has examined the relation between intelligence test scores and P300. Quicker onset of P300 activity following stimulus presentation typically has been associated with higher intelligence test scores. The relation between P300 onset and IQ has not been consistent, however, and depends in part on the intelligence test utilized.

Brain Size and Intelligence

Some investigators have examined the relationship between brain size and intelligence. For humans, the statistical relationship is modest but significant. Obviously, the finding is only correlational: Greater brain size may cause greater intelligence, greater intelligence may cause greater brain size, or both may be dependent on some third factor. Moreover, how efficiently the brain is used is probably more important than its size. For example, on average, men have larger brains than women, but women have better connections, through the corpus callosum, between the two hemispheres. So it is not clear which sex would have, on average, an advantage – probably neither.

The relationship between brain size and intelligence does not hold across species. Rather, there seems to be a relationship between intelligence and brain size relative to the rough general size of the organism (level of encephalization).

Genetic and Heritability Studies of Intelligence

Although numerous attempts have been made to identify genes that are critical to intelligence, no single gene has been conclusively identified and it looks as though there will be no 'gene' for intelligence to be found. Up to the present, investigators have conducted at least six genomewide scans for genes contributing to intelligence and other aspects of cognition. The data from these scans vary, but there are definitely some partial overlaps. In particular, the data suggest genes related to intelligence in regions on chromosomes 2q (in four out of the six investigations), 6p (for five of the six investigations), and 14q (for three of the six investigations). IQ QTL is a research project attempting to identify quantitative trait loci (QTL) responsible for genetic variation in intelligence. The investigators have sought to identify QTLs linked to intelligence. But positive findings have generally failed to replicate or generated weak signals that have not yet been convincingly replicated in independent samples. Deary and his colleagues have found that "there is still almost no replicated evidence concerning the individual genes, which have variants that contribute to intelligence differences." G. Davies and colleagues, in a study involving 3511 unrelated adults and almost 550 000 single nucleotide polymorphisms (SNPs), have found that genetic bases of intelligence are very widely distributed across genes rather than localized. They have estimated that 40% of the variation in crystallized intelligence and 51% of the variation in fluid intelligence is accounted for by linkage disequilibrium across genotyped common SNP markers and unknown causal variants. Little is known of genetic markers for the broader aspects of intelligence discussed later in this article.

Most attempts to investigate genes underlying intelligence have been indirect rather than direct, through studies of heritability. But heritability is itself a troubled concept. Heritability (also referred to as h^2) is the ratio of genetic variation to total variation in an attribute (such as intelligence) *within* a given population. As a result, the coefficient of heritability says nothing with regard to sources of between-population variation. The coefficient of heritability further does not tell us the proportion of a trait that is genetic in absolute terms, but rather, the proportion of variation in a trait that is due to genetic variation *within a specific population*.

Variation in a trait within a given population is referred to as phenotypic variation; genetic variation in a given population is referred to as genotypic variation. Thus, heritability is a ratio of genotypic variation to phenotypic variation. Complementary to heritability is environmentality, which is a ratio of environmental variation to phenotypical variation. Both heritability and environmentality are applicable only to populations, not to individuals. There is no way of estimating heritability for a particular individual, nor is the concept of heritability even meaningful for individuals.

Heritability is typically evaluated on a 0–1 scale, with a value of 0 signifying no heritability at all (i.e., no genetic variation underlying the trait) and a value of 1 indicating complete heritability (i.e., exclusively genetic variation in the trait). Heritability and environmentality add up to 1. Thus, if IQ has a heritability of 0.50 within a certain population, then 50% of the variation in scores on the attribute within that population is due (in theory) to genetic influences. This statement is completely different from the statement that 50% of the attribute is inherited. Similarly, if a trait has a heritability equaling 0.70, it does not mean that the trait is 70% genetic for any individual, but rather that 70% of the variation across individuals is genetic.

Thus heritability is *not* tantamount to genetic influence. A trait could be highly influenced by genes and yet have low heritability (or none at all). This is because heritability depends on the existence of individual differences. If there are no individual differences, there is no meaningful heritability (because there is a 0 in the denominator of the ratio of genetic to total trait variation in a given population). As an example, being born with two eyes is 100% under genetic control (with extremely rare exceptions of malformations not discussed here). Put another way, regardless of the environment into which a person is born, the person will have two eyes. But it is not meaningful to speak of the heritability of people's having two eyes, because there are no individual differences in the trait. Heritability is not one; rather, it is meaningless (because there is a 0 in the denominator of the ratio) and cannot be sensibly calculated.

Heritability has no fixed value for a given attribute such as intelligence. Although we may read about 'the heritability of IQ' (which, according to most theories, is not exactly the same as intelligence), there is no single fixed value of heritability that represents some true, constant value for the heritability of IQ or anything else. Heritability is dependent on numerous factors, but the most important single factor is the range of environments. Because heritability represents a proportion of variation, its value will depend on the amount of variation. As Richard Herrnstein pointed out, if there were no variation at all

in the environments in which people lived, heritability would be 1, because there would be no other source of variation. If there is wide variation in environments, however, heritability is likely to decrease.

In speaking of heritability, we must remember that genes always operate within environment contexts. All genetic effects occur within a reaction range. As a result, environment will likely have differential effects on the same genetic structure. The reaction range is the range of phenotypes (observable effects of genes) that a given genotype (latent structure of genes) for any particular attribute can produce, given the interaction of environment with that genotype. For example, genotype determines a reaction range for the possible heights a particular person can attain, but other factors, such as diseases, childhood nutrition, and the like may affect the adult height that is attained. Furthermore, if different genotypes respond differently to environmental variation, heritability will differ depending on the mean and variance of relevant factors in the environment. Thus, the statistic is not a fixed, constant value. There exist no purely genetic effects on behavior, as would be demonstrated dramatically if a child were raised in a small closet with no stimulation. No genotype would allow an individual's intelligence to flourish in such an environment. Genes thus express themselves through covariation and interaction with the environment.

Because the value of a given heritability statistic is relevant only under existing circumstances, the statistic does not and cannot address the modifiability of a trait. A trait could have a high level of heritability and nevertheless be highly modifiable. The heritability statistic pertains to correlations, whereas modifiability pertains to mean effects. For example, height has a heritability of over 0.90. Yet height also is highly modifiable, as shown by the fact that average heights have risen substantially over the past several generations.

The heritability of intelligence is typically estimated as between 0.4 and 0.8. The value typically depends on the method used to estimate heritability, such as studies of degrees of relatedness (e.g., identical vs fraternal twins) or identical twins reared apart. The studies are hard to interpret, in part because their assumptions are not always met. For example, identical twins reared apart are not randomly assigned to environments so that one cannot cleanly separate genetic from environmental variation.

Matters are complicated by the fact that heritability estimates vary across populations. For example, estimates of the heritability of IQ in twin studies carried out in the former Soviet Union tended to be higher than they were in comparable studies conducted within the United States. This observation made sense in terms of our discussion above: Environmental variation in Russia under the Soviet regime was relatively constrained; most people lived in roughly comparable environments. As a result, heritability estimates were higher. Most of the IQ heritability studies up to today have been carried out in nations within the developed world. Relatively little information exists regarding the heritability of IQ in the developing world, although what evidence there is suggests moderate heritability in these nations as well.

Heritability also varies as a function of socioeconomic status (SES). Eric Turkheimer and his colleagues have found that heritability is very substantially higher in higher SES families than in lower SES families. In particular, at the lowest levels of SES, shared environment accounted for almost all of the variation in IQs whereas at the highest levels shared environment accounted for practically no variation.

In sum, heritability estimates do not explain in any meaningful sense genetic regulation of human behavior. Furthermore, they do not provide accurate estimates of the strength of the genetic regulation. Rather, as geneticist Elena Grigorenko has pointed out, genes act within the context of environments and their effects must be understood within these contexts.

Cognitive-Contextual Theories

Cognitive-contextual theories deal with the way that cognitive processes operate in various environmental contexts. Two of the major theories of this type have been proposed by Howard Gardner and Robert Sternberg.

In 1983 Howard Gardner proposed a theory of what he called "multiple intelligences." In the 2006 version of the theory, the multiple intelligences include, at minimum, linguistic, logical-mathematical, spatial, musical, bodily kinesthetic, naturalist, interpersonal, and intrapersonal intelligences. Gardner has also speculated as to the existence of an existential intelligence.

An alternative theory also taking into account both cognition and context is Robert Sternberg's 'triarchic' theory of successful intelligence. According to the initial version of Sternberg' theory, intelligence has three aspects: analytical, creative, and practical. Analytical intelligence is what is measured by conventional intelligence tests. But such tests fail to measure creative intelligence – abilities in generating new ideas that are useful – and practical intelligence – the application of intelligence to everyday life, or what may be called common sense. In more recent versions of the theory, Sternberg has suggested that wisdom – the application of one's knowledge and skills toward achieving a common good, over the long and short terms, through the infusion of ethical values, is also an important part of successful intelligence.

Peter Salovey and John Mayer have proposed the construct of emotional intelligence. It then was popularized by Daniel Goleman in a book on emotional intelligence. It is the ability to perceive accurately, appraise, and express emotion; the ability to access and/or generate feelings when they facilitate thought; the ability to understand emotion and emotional knowledge; and the ability to regulate emotions to promote emotional and intellectual growth. Several tests are now available to measure emotional intelligence. They generally show modest to moderate correlations with conventional tests of intelligence.

Development of Intelligence

There have been diverse approaches to studying the development of intelligence. Psychometric theorists, for instance, have sought to understand how intelligence develops in terms of changes in the factors of intelligence over time and changes in the amounts of the various abilities that children have. For example, the concept of mental age was popular during the first half of the twentieth century. A given mental age was believed to represent an average child's level of mental functioning for

a given chronological age. Thus, an average 10-year-old would have a mental age of 10, but an above-average 8-year-old or a below-average 12-year-old might also have a mental age of 10 years. The concept of mental age has fallen into disfavor, however, and is now used only rarely. The concept does not work well over a chronological age of roughly 16, and its assumption of perfectly smooth continuous mental development is questionable.

The Theory of Jean Piaget

Jean Piaget, a Swiss psychologist, suggested that the child explores the world, observes regularities, and makes generalizations, much as a scientist does. Two fundamental cognitive processes are apparently at work in somewhat reciprocal fashion. Assimilation involves incorporating new information into an already existing cognitive structure. Accommodation involves forming a new cognitive structure to incorporate new information. Cognitive development, according to Piaget, represents a dynamic equilibrium between these two processes of assimilation and accommodation.

Piaget also postulated that there are four major periods in intellectual development. The first, the sensorimotor period, extends from birth until roughly 2 years of age. During this period, a child learns how to modify reflexes to make them more adaptive, to coordinate actions, to retrieve hidden objects, and, eventually, to begin representing information mentally. During the second, preoperational period, from about 2–7 years of age, a child experiences the growth of language and mental imagery. He or she also learns to focus on single perceptual dimensions, such as color and shape. The third, concrete-operational period, is from about 7–12 years of age. It is the period during which a child develops an important set of skills that are referred to as conservation skills. The child will recognize that substances stay the same in amount, regardless of their form. Finally, children emerge into the fourth, formal-operational, period, which begins at about age 12 and continues throughout life. The formal-operational child develops thinking skills in all logical combinations and learns to think with abstract concepts.

Post-Piagetian Theories

Later so-called "post-Piagetian" theories of intellectual development, which have been heavily influenced by Piaget, have taken several courses. One, that of Patricia Arlin, has been to expand on Piaget's work by suggesting a possible fifth, adult, period of development, such as problem finding. A second course has been to suggest periods of development related to but different from those suggested by Piaget. A third course has been to accept that intellectual development occurs through the periods Piaget proposed, but to hold that the cognitive bases of development differ from those recognized by him. Some of these theories emphasize the importance of memory or knowledge rather than reasoning capacity.

The Theory of Lev Vygotsky

Lev Vygotsky, a Soviet psychologist, suggested that intellectual development may be largely influenced by a child's interactions with others: A child sees others thinking and acting in certain ways and then internalizes and models what is seen. Vygotsky also proposed the notion of a zone of proximal development (ZPD), which is the range of ability between a person's observable level of ability and the person's latent capacity. This latent capacity is not directly observable but may be detected by providing a context in which the latent capacity may be revealed and expressed. The ZPD is sometimes termed the zone of potential development.

Measuring Intelligence

Early Historical Background

The publication in 1859 of Charles Darwin's *The Origin of Species* had a profound effect on many lines of scientific work. Darwin suggested that the capabilities of humans are, in some sense, continuous with those of lower animals. Hence, they can be understood through scientific investigation. One person who was strongly influenced by Darwin's thinking was Sir Francis Galton, Darwin's cousin. For 7 years – between 1884 and 1890 – Galton maintained a laboratory at the South Kensington Museum in London. For a small fee, visitors could have themselves measured on a variety of psychophysical tasks. These tasks included weight discrimination and sensitivity to musical pitch. Galton believed that these tests measured more than just psychophysical abilities. He believed that psychophysical abilities are the basis of intelligence and, hence, that his tasks were measures of intelligence. Galton's intelligence test, therefore, required a person to perform simple tasks, such as deciding which of two weights was heavier or showing how forcefully he could squeeze his hand. The Galtonian tradition was taken to the United States by the psychologist James McKeen Cattell.

The IQ Test

A more influential tradition of mental testing was developed in France by Alfred Binet and his collaborator, Theodore Simon. In 1904 the minister of public instruction in Paris named a commission to study or create tests that would insure that intellectually deficient children received an adequate education. The minister was also concerned that certain children were being placed in classes for the retarded not because they were intellectually deficient but because they had behavior problems, and teachers did not want them in their classrooms. Binet and Simon proposed that tests of intelligence should measure skills such as judgment, comprehension, and reasoning – the same kinds of skills measured on most intelligence tests today. Binet's early test was taken to the United States by a Stanford University psychologist, Lewis Terman, whose version came to be called the Stanford–Binet test. This test has been revised frequently and continues to be in use.

The Stanford–Binet test, and others like it, have traditionally yielded at the very least an overall score referred to as an intelligence quotient, or IQ. In its most recent form, this test, as well as the Wechsler Adult Intelligence Scale and the Wechsler Intelligence Scale for Children, yield an overall IQ and other scores as well.

More recent tests of intelligence have expanded the range of abilities tested. For example, in 1997, J.P. Das and Jack Naglieri first produced a test, the Cognitive Assessment System, based on a theory of intelligence first proposed by a Russian psychologist, Alexander Luria. The test measures planning abilities, attentional abilities, and simultaneous and successive processing abilities.

IQ was originally computed as the ratio of mental age to chronological (physical) age, multiplied by 100. It is thus sometimes referred to as a ratio IQ. For example, if a child of 8 had a mental age of 10 (that is, performed on the test at the level of an average 10-year-old), the child was assigned an IQ of $(10/8) \times 100$, or 125. If the 8-year-old had a mental age of 6, the child's IQ would be $(6/8) \times 100$, or 75. A score of 100, whereby the mental age equals the chronological age, is average.

As discussed above, the concept of mental age has fallen into disrepute, and few tests continue to involve the computation of mental ages. Many tests still yield an IQ, but it is most often computed on the basis of statistical distributions. The scores are assigned on the basis of what percentage of people of a given group would be expected to have a certain IQ. Scores computed in this way are called deviation IQs.

The Distribution of IQ Scores

Intelligence test scores follow an approximately normal distribution, meaning that most people score near the middle of the distribution of scores. Scores drop off fairly rapidly in frequency in either direction from the center of the distribution. For example, on the IQ scale, about two-thirds of all scores fall between IQs of 85 and 115, and about 95% of scores fall between 70 and 130. Put another way, only one out of 20 scores differs from the average IQ (100) by more than 30 points.

Many psychologists now believe that IQ represents only a part of intelligence, and intelligence is only one factor in both developmental disability and intellectual giftedness. Most current definitions of mental retardation stress adaptive skills as well as IQ, and they also emphasize attributes such as creativity, motivation, and achievement in conceptions of giftedness.

Intelligence: History of the Concept

Abstract

As a traditional division of the human soul, intelligence had long been of importance to Western philosophers and theologians. Nonetheless, before the eighteenth century intelligence, as a description of overall mental capacity, had little provenance on either side of the Atlantic. Intelligence, as a separate area of research, began to attract attention as growing curiosity about the nature of human differences meshed with the turn to scientific methods as privileged forms of explanation. This article explores that history and highlights how the Intelligent Quotient version of intelligence has come to dominate Western understandings of the concept.

Introduction

In its modern, Western guise the concept of intelligence has seemed inextricably linked to the technology for measuring it, the Intelligence Quotient (IQ) test. Developed in its modern form in 1905 by the French psychologist Alfred Binet (1857–1911) and his collaborator Théodore Simon (1872–1961), the intelligence scale and the practices of measuring intelligence it spawned spread quickly to many parts of the world, including England, Spain, Germany, Latin America, and preeminently the United States. This new technology, however, did not resolve fundamental questions about the nature of intelligence, including a precise definition of what it was, whether it was a product of heredity or environment or both, and whether it was one thing or many. To this day, these issues continue to bedevil psychologists who study intelligence and to haunt many of the public debates about education and merit that rely, either explicitly or implicitly, on particular conceptions of intelligence. In general, one can say that in most current uses of the term, 'intelligence' refers to some sort of overall mental capacity, and one that particularly highlights reasoning, problem solving, and abstract thinking. Nonetheless, research across cultures and historical periods has shown that the specific characteristics attached to the notion of overall mental ability can vary greatly, as can the importance assigned to intelligence as an individual or group-level characteristic.

The direct antecedents of the word 'intelligence' lie in the Latin *intelligentia* or *intellegentia* meaning "the action or faculty of understanding," itself derived from the Latin *intellegere* meaning 'to understand.' As one of the traditional divisions of the human soul (along with the emotions and the will), intelligence was a concept that had long been of importance to Western philosophers and theologians, especially in their attempts to differentiate human beings from other species in the animal world. Nonetheless, up to the eighteenth century it was not a word that evoked much interest on either side of the Atlantic, particular in its modern sense as a description of a person's overall mental capacity. Intelligence began to attract attention in the West as growing curiosity about the nature of human differences meshed with the turn to scientific methods as a privileged form of explanation. This article will explore some of that history and suggest how the development of the concept was intimately related to the particular cultural circumstances in which it was formulated and used.

Species, Groups, and Intelligence

Human nature was a topic of wide resonance within many intellectual fields during the eighteenth century. Not only were virtually all the emerging human sciences engaged in an intensive exploration into the fundamental characteristics of human beings, many of the most important developments in political philosophy also relied on notions about human nature as bedrock for their investigations. Nonetheless, few philosophers or other writers of the period gave much attention to intelligence per se. Rather, they tended to focus on other, somewhat related, concepts, such as 'faculties' and 'talents' and 'sensations' and, most especially, 'reason' and 'virtue.' While it is clear that there was widespread agreement that human beings differed in their mental powers, the origin, significance, and even the sheer number of those differences were all issues that elicited either a multitude of opinions, or no particular view whatsoever. In general, single all-encompassing approaches to understanding mental capacity, such as 'intelligence,' tended to be used only in limited and very particular contexts.

Interest in some sort of mental attribute characterizing overall ability to think or reason can be traced in the west at least back to the ancient Greeks and Aristotle's (384–322 BCE) definition of humans as creatures who reason. Nonetheless, intelligence began to become an object of direct scientific investigation only toward the end of the eighteenth century, when Carl Linnaeus (1707–78), the Comte de Buffon (1707–88), Johann Friedrich Blumenbach (1752–1840), and other naturalists began to compare humans systematically with other animals in the course of developing their grand taxonomies of life. Such comparisons often focused on differences in levels of mental ability, and were linked by many to the notion of the great chain of being, a linear scale that stretched from the lowest organisms through humans and up to God. The Dutch anatomist and artist Peter Camper (1722–89), for example, proposed in the 1760s that a scale of intelligence across the animal kingdom could be erected on the basis of a particular physiological feature, the facial angle, which for the first time

allowed intelligence to be converted into a type of measurable characteristic, though one operating primarily at the level of species or groups. Over the next century and a half a number of other physical features were also evaluated as stand-ins for direct determinations of degree of intelligence, with most physical anthropologists according particular significance to cranial capacity and brain weight. Elaborate programs of measuring hundreds of skulls were carried out throughout Europe and the United States, with the results frequently used to provide scientific sanction for common beliefs about the intellectual inferiority of certain groups, most especially Africans and women, on the basis of the greater proximity of their mean skull or brain sizes to those for the nonhuman primates. As more data were collected, however, extreme variations were found both within and between groups, rendering group-level rankings in the eyes of many largely meaningless. At the same time, the efforts of women in feminist movements and blacks in antislavery campaigns produced powerful denunciations of the entire project of creating hierarchies of intelligence based on physical characteristics.

Until the latter part of the nineteenth century, arguments about intelligence largely focused on the intellectual capacity of groups. Intelligence as a personal characteristic distinguishing one individual from another generated little systematic interest, save for medical concern with diagnosing the mentally deficient and legal interest in those of unsound mind. Mental philosophy and the emerging discipline of 'scientific' psychology were preoccupied with the universal characteristics of human reason and, in the case of psychology, with the process of subjecting mental features to new laboratory techniques being imported from physiology. As the evolutionary theories of Charles Darwin (1809–82) and Herbert Spencer (1820–1903) became more broadly accepted, however, interest grew in the overall mental power of individual organisms, because mental capacity was deemed to be a critical characteristic shaping the organism's adaptation to its environment. Greater pressure to understand the nature of individual differences was also developing as the result of a number of institutional and social changes occurring throughout the West. The spread of universal primary education, the increase in urban concentrations of workers, and the expansion of factory methods of production, along with the rapid growth in asylums for the mentally deficient, all provided many more opportunities to engage in systematic comparisons at an individual level, and thus helped to make intellectual differences much more visible and socially meaningful.

Intelligence and Its Tests

During the late nineteenth century, a number of investigators began to explore the meaning of individual differences, including those associated with overall level of intelligence. In England, Francis Galton (1822–1911) carried out an extensive program of quantifying human mental and physical characteristics (anthropometrics) toward the goal of identifying superior members of the human stock. His *Hereditary Genius* (Galton [1869]1972) argued that innate differences in overall superiority existed within human groups, that those differences were mental in origin, and that they were inheritable. Galton's work helped to initiate widespread enthusiasm for anthropometry, one that persisted until the end of the century. It was also a basis for his promulgation of the science of eugenics, which conceived of human progress in biological terms and advocated improvement in the quality of the breeding stock through encouraging marriages and child bearing among the most 'fit' (i.e., most intelligent) and restricting them among the least.

On the other side of the Channel, psychologist Alfred Binet, one of the pioneers in the development of *psychologie individuelle* in France, conducted a wide range of investigations at the turn of the century into the nature of human mental ability. As one of these projects, in collaboration with Théodore Simon Binet developed the initial version of what would become the first successful individual intelligence assessment instrument, the Binet–Simon Intelligence Scale (1905). The scale was comprised of a series of age-related tasks whose purpose was to reveal whether an examinee's overall intelligence was developing at a 'normal' rate. The measuring aspect of the scale was enhanced following its revisions in 1908 and 1911, when the test-giver's discretion in deciding when answers were right or wrong was severely reduced and results from the testing were reported in terms of mental age (M.A.), which facilitated conceiving of intelligence as a physical and quantifiable object.

Binet's death soon after the publication of the 1911 scale robbed the Binet–Simon of its most effective champion in France, and interest in intelligence testing there remained limited. Such was not the case elsewhere in the West, however, most especially in the United States. With the help of American psychologist Henry Herbert Goddard (1866–1957), who introduced the 1908 version of the scale to his fellow U.S. psychologists in 1910, the Binet–Simon was adopted with enthusiasm. Rival versions of the test were soon produced in great numbers and a vogue for testing developed that never completely vanished.

Stanford University psychologist Lewis M. Terman's (1877–1956) 1916 revision of the scale, his Stanford–Binet (Terman, 1916), did much to cement the place of intelligence testing within the American intellectual and cultural landscape. Thoroughly overhauled for an American population, the Stanford–Binet provided clearer age demarcations and popularized a new way of quantifying mental ability first championed by William Stern (1871–1938), the Intelligence Quotient (IQ), a ratio of mental age to chronological age (times 100) designed to remain constant over time. Terman celebrated this feature of IQ, arguing that it provided a measure of an individual's innate mental ability. He also suggested that IQ could be used to help make a variety of social decisions, including an individual's occupational choice, level of appropriate education, and possible need for institutionalization.

While not every mental tester was as certain about the implications of IQ as Terman, during the 1920s use of intelligence tests in a variety of contexts spread widely, facilitated by the creation of a group mental test (Army Alpha) for the World War I war effort that allowed 1.75 million U.S. army recruits to be assessed without needing the time-consuming one-on-one methods of the Stanford–Binet. Terman's individual scale, revised in 1937 and 1960, however, remained the gold standard for measurements of intelligence, though its preeminence began to be challenged starting in the 1940s with the creation

by David Wechsler (1896–1981) of the Wechsler Intelligence Scale for Children (WISC) and the Wechsler Adult Intelligence Scale (WAIS), instruments that generate assessments of verbal and nonverbal intelligence as well as an IQ.

The Nature of Intelligence

Concomitant with the rise of intelligence testing came a series of debates over the characteristics of the object being measured. In 1904 British psychologist Charles Spearman (1863–1945) used early test data to argue for the unitary nature of intelligence, explaining performance on mental tests in terms of general intelligence (*g*) and specific abilities (*s*). While numerous researchers – including Karl Pearson (1857–1936), Goddard, and Terman – accepted his analysis, others were skeptical, insisting instead that intelligence was composed of a number of primary independent abilities. Edward L. Thorndike (1874–1949) in the United States was among the first to articulate this position. During the 1920s, he was soon joined by two statistically sophisticated psychologists, L.L. Thurstone (1887–1955) in the U.S. and Godfrey Thomson (1881–1955) in the U.K. Both used mathematical methods similar to Spearman's (factor analysis) to show, not that there was one central factor, as had Spearman, but that there were a small number of significant and independent abilities. In the period after World War II, psychologists continued to put forward a range of interpretations of the composition of intelligence: while Hans Eysenk (1916–97) remained convinced of the reality of *g* (general intelligence), for example, Philip E. Vernon (1905–87) proposed a hierarchical model of intelligence that inter-linked specific skills, general abilities, and overall intelligence, and Joy P. Guilford (1897–1987) contended that intelligence was composed of as many as 150 independent factors. Later influential additions to these conceptualizations included Howard Gardner's (1943–present) seven discrete types of intelligence and Robert J. Sternberg's (1949–present) triarchic model of intelligence.

Overshadowing all of the arguments over intelligence, however, has been the nature–nurture question, particularly with regard to racial, ethnic, and socioeconomic groups. Figures such as Galton, Spearman, Pearson, and Terman argued early in the twentieth century strenuously for the nature position, with Galton producing studies on identical twins that have served as a model to this day for investigations into the relative weights of heredity and environment. During the 1900s to 1930s, when eugenics was at the apex of its popularity, arguments in favor of intelligence as an inheritable biological entity ran strong, and were used to justify calls for immigration restriction and for sterilization of the mentally 'unfit,' as well as for the creation of multitracked secondary schools. Claims about the 'inferiority' of non-European racial groups had been long-standing in the West, buttressed from the middle of the nineteenth century on with arguments about differences in overall levels of intelligence. During the early twentieth century these arguments continued to be promulgated using data on intelligence produced by the new intelligence tests, and indeed to be extended to less favored segments of the so-called 'white race,' including lower socioeconomic groups and peoples deriving from parts of southern and eastern Europe. There was also a particular worry about those individuals feared to be of subnormal intelligence, with professional scholars and public figures often decrying what they termed 'the menace of the feebleminded.'

At the same time, however, anthropologists were beginning to put renewed emphasis on culture as the primary determinant of human behavior, claims strengthened during the middle of the century by studies carried out especially at the Iowa Child Welfare Research Station, where IQ was found to change depending on nutrition and educational environment. Moreover, during the 1920s and 1930s a number of psychologists and sociologists in the United States, including many prominent African-American scholars, challenged much of the data on which claims about group-level differences in mental ability were based, demonstrating that the World War I testing data, for example, could be more convincingly interpreted as showing that intelligence scores were influenced markedly by the quality of education received.

During the post-World War II period the debate continued to be pressed from both sides, with increasingly sophisticated twin studies showing high IQ correlations between identical twins separated at birth, while at the same time other researchers were teasing out ever more complicated connections between intelligence development and such factors as nutrition, family child-rearing practices, socioeconomic status, and quality of education received. In the 1980s, James R. Flynn among others pointed out the significant increases in IQ test scores around the globe (now known as the 'Flynn effect'), and used those dramatic changes to argue that intelligence tests were capturing only limited aspects of the underlying entity called intelligence and that performance on these tests was strongly affected by a range of environmental factors. There was also a wholesale retreat on claims about intelligence at the level of groups, with most mainstream researchers arguing that group-level differences, even if they existed, were more than swamped by individual variation and environmental factors.

While few experts would deny the influence of both genes and the environment, the vociferous debate in the mid-1990s over *The Bell Curve* (Herrnstein and Murray, 1994), with its claims that IQ is hereditary and a prime determinant of an individual's future, indicates that broad disagreements persist about intelligence and show little likelihood of quick resolution. What they reveal as well is that the language of native intelligence has remained a powerful vehicle for discussions of a range of social issues, from the organization of an educational system to the value of affirmative action programs to the just allocation of social resources. Because of its associations with individual merit and its history of use for racial and class discrimination, intelligence continues to attract both strong proponents and vigorous critics, and remains a concept with wide cultural and political resonance.

Intelligence in Cultural, Social and Educational Context

Andreas Demetriou, University of Nicosia Research Foundation, University of Nicosia, Nicosia, Cyprus

Abstract

This article reviews recent research on human intelligence and intellectual development and the effects of culture and other social factors on both.

It also capitalizes on recent literature on how intellectual development may be strengthened by education. Contrary to a common depiction of human intelligence as a unitary trait that is invariant across time, space, and cultural context, this article argues, with Sternberg (2004), that "Intelligence cannot be fully or even meaningfully understood outside its cultural context."

Imagine persons of different ages in different cultures trying to make sense of various situations, solve problems, or make necessary decisions relevant to their age:

1. A 3-year-old toddler in New York, Athens, or Beijing trying to figure out how to make his brand new toy car move around in the room, ask for some help from the dad, or pretend that he is driving his dad's car. Alternatively, imagine a toddler in a remote small village in Africa, riding a rod pretending that it is a horse or throwing little stones to hit a small bird.
2. A 10-year-old trying to understand history or biology as presented in a school book, solve algebra problems, figure out why her best friend is angry with her and restore the relation, or convince her mother to let her meet with friends. Alternatively, imagine a child in one of the South American megacities, making a living through selling and buying fruits on the street.
3. A 16-year-old writing an essay on how principles in physics underlie the operation of mobile phones, choose a course of studies that will end up in an occupation, or make political choices based on discussions with friends, teachers, parents, and public debate (on TV or through the Internet) about governments decisions. Alternatively, imagine an adolescent trying to pass the induction tests of his tribe in the Amazon forest to become a member of the adults of the tribe or an adolescent in the Pacific islands trying to learn how to navigate from one island to the other.

However different they appear, all of these situations require from the person to specify what the problem is about and combine presently available information, previous knowledge, and thought to find a pertinent solution. In short, they require intelligence. Moreover, all of these problems are similar in some respects over all ages and cultures and different in some other respects.

To understand the human mind and intelligence, one of the mind's important manifestations, the modern science of the human mind tries to answer the following questions (Carroll, 1993; Demetriou et al., 2010; Jensen, 1998; Piaget, 1970):

1. What are the cognitive processes underlying intelligence? That is, how is information represented, connected and processed, understood, transformed, and used for the sake of learning, problem solving, and decision making?
2. What is general and what is specific in intelligence? That is, what is common across different domains of knowledge, such as mathematics, literature, or law, or different types of activity and skill, such as music, drawing, or dancing and what is particular to each of these domains?
3. What is stable and what is changing with development in intelligence?
4. Why do individuals differ in intelligence?
5. What is the contribution of the environment and culture to these differences?
6. Can intelligence be changed by education?

What Is Involved in Intelligence?

The human mind emerges from the functioning of the human brain. The human brain is an extremely complex system that evolved to enable us to know the world and cope with its demands in the sake of survival and continuation. We are connected with the world through our senses. Vision provides access to the visible aspects of the world. The space we move in, the objects we see, their color, shape, size, and number, their positions relative to each other, and their interactions, are all known through our eyes and the parts of the brain that are responsible to represent and process the information collected by the eyes. Hearing provides access to sound. All sorts of sounds produced by the natural environment and other living beings, including humans, can become known through the ears and the parts of the brain that are responsible to record and process sound. The other senses, such as smell, taste, and touch, provide other kinds of knowledge about the world. Information coming from each channel has properties that are specific to it. Through time, the human brain evolved structures and processes specializing in the processing of the various types of information provided by the senses and in the integration of different kinds of information into holistic and systematic representations enabling accurate understanding, appropriate decision making, and efficient problem solving (Jung and Haier, 2007).

The description above applies to all other organisms with a brain, to degrees varying with the complexity of their brain. It is unique to humans, however, that, they may draw knowledge and solutions to problems from stored pools of knowledge and

ideas. These are cultural products that were made initially possible because humans evolved to have a communication system that enables them to share knowledge and ideas. That is, first they acquire language, at least 100 000 years ago (Sampson et al., 2009) and then arbitrary symbol systems that stand for language, primarily writing, about 3200 years ago (Daniels and Bright, 1996), that render present knowledge and ideas virtually eternal. As a result, knowledge and problem solving becomes collective and, in principle, always available and always revisable. Obviously, the stored knowledge of different cultures reflects the history of each of them. Education is the institution that was developed through the millennia as a means for the induction of each individual into his or her own culture (Mithen, 1996).

The human mind has been the focus of three research traditions in psychology, since the late nineteenth century: the cognitive, which focused on cognitive functions and processes (Sternberg, 2011), the differential, which focused on individual differences in intellectual ability (Mackintosh, 1998), and the developmental tradition, which focused on cognitive development (Case, 1985). Because of priorities in each, research questions, methods, and theoretical constructs differed between the three traditions, especially at their early years. With time, however, the three traditions did interact with and informed each other in theory and methods. This interaction led to considerable convergences in how the human mind is analyzed and studied. According to all traditions, the human mind (1) learns actively from interactions with the world, (2) represents its interactions in mental models which are used (3) to guide further encounters, especially when they are new and unexpected. The success to deal with unexpected encounters is a measure, in all traditions, of the overall functional efficiency of the mind, gauged vis-à-vis the current situation (in the cognitive tradition), other individuals (the differential tradition), or the age of the individual (the developmental tradition). Also, all traditions are reductionist, in that they attempt to reduce models that represent the world and guide interactions with it into simpler processes aiming to capture the capacity of the mind to learn, model, choose between, and use representational systems according to current or predicted and planned goals and needs (Demetriou et al., 2010, 2011; Kazi et al., 2012).

Research and theory in these traditions converge on the assumption that the human mind is a very complex universe of processes that cooperate for the sake of understanding, problem solving, and learning. These processes are organized into systems that carry out different tasks during any understanding or problem solving task. Specifically, a set of processes interface the mind with different aspects of the environment. A second set are responsible to meet the representational and processing needs activated by the environment-oriented processes. A third set is responsible to connect and integrate information and operations vis-à-vis the goal of the moment. Finally, a fourth set of processes are responsible for the monitoring, control, and regulation of the processes activated at a given moment, if needed. That is, the four types of processes are as follows: *specialized structural systems or domains of mind*, *representational capacity*, *inference*, and *consciousness*. **Figure 1** highlights this architecture (see Demetriou et al., 2010, 2011; Hunt, 2011). These processes are involved in everyday regular functioning but also in creative mental functioning of gifted persons (Kaufman and Baer, 2006).

Figure 1 The general architecture of the human mind.

Domains of Intelligence

Discussion about the domains of intelligence goes on for decades. In the classical psychology of intelligence, there is general agreement about three domains of thought: language, space, and number. Command and versatility in using language, such as the comprehension and use of words, ability to mentally orient in space and grasp the relations of objects in space, such as when one must put together the pieces of a puzzle to form an integrated picture, and the ability to deal with numbers and quantitative relations, are examples of fundamental abilities in each of these three domains. Causality is recently recognized as another domain (Carey, 2009). That is, the ability to grasp how and when objects or persons cause changes in each other. In the recent years the understanding and dealing with one's own and the other persons' emotions, feelings, and thoughts is regarded as a separate domain of psychological/social intelligence. The current discussions about emotional intelligence or interpersonal and intrapersonal intelligence in Gardner's (1983) theory of multiple intelligences stand for this domain. Gardner also added kinesthetic and musical intelligence to these domains. The domain of biology may be a separate domain of thought that enables understanding of the phenomena of life and the principles underlying the behavior and condition of living beings (Carey, 1985).

Each of the domains involves three types of processes, summarized in **Table 1**. Specifically, the domains involve (1) core processes, (2) mental operations, and (3) knowledge and beliefs. Core processes are innate and geared in perception, as noted earlier. Examples are categorical perception on the basis of color, the perception of depth in the spatial system, or subitization in the quantitative system – that is, the ability of humans and other animals to automatically perceive numerosity for sets of up to three to four elements. They are present from the very first few of weeks of life if not at birth (Carey, 2009), they are the result of our evolution as a species, and they form the background for the development of the other processes in domains. With development, core processes yield mental operations that are increasingly self-guided. For example, categorization according to color in the categorical system, arithmetic operations in the quantitative system, isolation of variables in the causal system, mental rotation in the spatial system, perspective taking in the social system. Finally, the functioning of core processes and mental operations generates and updates conceptual and belief systems pertaining to the physical, the biological, psychological, and the social world: for example, money values and rules underlying everyday transactions in the quantitative domain; mental images, mental maps, locations, scenes, or layouts stored in memory in the spatial domain; representations about physical events in the causal domain or social events in the causal domain (Carey, 1985, 2009).

Domain specificity is a long-debated issue in psychology. In the domains, domain specificity varies according to level of the processes concerned. Core processes are highly domain-specific because they are constrained by perceptual

Table 1 Processes and levels in the organization of cognitive domains

Domain	*Core processes*	*Mental operations abstraction/induction*	*Knowledge and beliefs*
Categorical	Perception of similarity.	(Bayesian) inductive inferences based on similarity–difference relations. Semantic and logical relations in class hierarchies.	Conceptions and misconceptions about the world (objects, animate beings, persons), units of matter (e.g., substance, molecules, atoms, particles, etc.).
Quantitative	Subitization; pointing, counting, object arrangement (arithmetic operations).	Number alignment, induction of the mental line, proportionality.	Factual knowledge about the quantitative aspects of the world, street and supermarket mathematics, quantitative dimensions (e.g., weight, volume, area, etc.), algebraic and statistical inference rules.
Spatial/time	Location, object, size, depth, orientation perception; formation of mental images.	Mental rotation, image integration and reconstruction, location and direction tracking and reckoning.	Stored mental images, mental maps, and episodic representations and scripts about objects, locations, scenes, or occurrences.
Causal	Perception of interactions or associations in spacetime.	(Bayesian) induction of causal relations (e.g., necessary and sufficient, necessary and non-sufficient, etc.); causal search (trial and error); hypothesis formation; experimentation (isolation of variables).	Knowledge, attributions and understanding of the reasons underlying physical, biological, and social events.
Social	Recognition of conspecifics, species-valued stimuli, imitation.	Theory of mind (induction of intentions, mental states, and beliefs); decentering and taking the other's perspective.	System of social attributions about other persons, traditions, customs, and ideologies in groups, societies, and cultures.
Language and symbolic systems	Grasp of grammatical and syntactical structures of language.	Truth/falsity identification; induction of relations between "truths"; differentiation of the contextual from the formal elements; elimination of biases from inferential process; securing validity of inference.	Knowledge about grammar, syntax, and logical reasoning; metalogic about inference; awareness about knowledge production and validation processes.

channels and they are activated by specific patterns of information in the environment. Mental operations are by and large domain-specific but they are subject to training and coordination between domains, as when for instance we use numbers from the quantitative system to represent spatial relations in the spatial domain or causal relations in the causal domain. Knowledge and beliefs systems are built on the common ground of the general processes and mental operations described here but they have a large degree of specificity. For example, the disciplines of physics, biology, and psychology focus on the natural, the biological, and the human world, respectively. They all require all of the systems of mind described here to be grasped, probably to varying degrees. At the same time, each is expressed in discipline-specific semantic and rule networks that need to be mastered as such.

Abstraction and Inference

The brain is a system that encodes at one and the same time the past of an organism and its possibilities for the future. Intelligence is the functional expression of the ability to use the past in the sake of the future by enabling the individual to capitalize on his past to make decisions and find solutions for new problems. Abstraction is the fundamental process for the unification of learning and mental experiences. The ability to recognize common patterns in the flow of information, connect them into new concepts, and use them for the acquisition of new knowledge is present from birth, if not earlier in the womb (Tenenbaum et al., 2011). Relations are recognized on the basis of *similarity* between objects or concepts (e.g., color pulls together very diverse objects just because they have the same color). *Inference* carries properties from one situation or concept to another on the basis of similarity and probabilistic trends in the pattern of events. That is, missing information in a target situation is *induced* or *inferred* because the two situations are similar in some respects so that characteristics of the known situation or concept are ascribed to the base situation on the basis of their other similarities (it moves on its own so it is a living being – even without legs).

Inductive, analogical, and deductive reasoning are the main types of inference. Inductive reasoning may involve any kind of representation, such as perceptions, mental images, or propositions, and it generates relations that are only likely. Analogical reasoning is inductive reasoning applied on relations as such (e.g., London is to the United Kingdom what Paris is to France – it is the capital of). Deductive reasoning is applied only on propositions or other symbols which stand for propositions. Thus, inference in deductive reasoning transfers meaning from one set of propositions (the premises) to other propositions (the conclusion) and it always proceeds from the general (the premises) to the specific (the conclusion). In deductive reasoning if the premises are valid their conclusion is also valid and it follows necessarily from the premises (e.g., Birds fly, Guzy is a bird, it flies – even if Guzy is an Ostrich and it therefore does not fly).

Tests of intelligence always include problems addressed to these kinds of reasoning in various forms. For example, the Raven progressive matrices test (Raven and Raven, 2008), a famous test of inductive reasoning, examines the ability to find relations between visual figures and use them to specify what is missing from a pattern. Analogical and deductive reasoning is examined in various contexts, such as the specification of analogical relations between number series (e.g., 1, 5, 3, 2, 6, 4, 3, 7, ?) or concepts as in the example above about countries and their capital.

Representational Capacity

To induce relations, interrelate concepts and premises and draw conclusions, and plan solutions for problems, the relevant information and concepts must be kept in mind for as long as needed. Working memory, short-term storage, and episodic memory are terms used to refer this capacity. A common measure of working memory is the maximum amount of information and mental acts that the mind can efficiently activate simultaneously. Baddeley's (1990, 2012) model is widely regarded as a good approximation to the architecture of working memory. According to this model, working memory consists of four systems. Specifically, there are two modality-specific storage systems, namely the phonological loop and the visuospatial sketchpad, which store acoustic and visual information, respectively. There is also a central executive. This is an attention-controlling system that sustains and coordinates processing in the specialized storage systems by processes such as selection of the to be remembered information and its updating so that it is lost. These processes are effortful and conscious and they compete for the available representational resources with the specialized storage buffers. Finally, there is an episodic buffer capable of integrating information across systems into unitary episodic representations. The episodic buffer ensures the production of integrated mental products and it preserves time and the subjectivity of experience. The capacity of the storage systems and the capacity needs of the central executive set the general limits for the complexity of information and processing that can be represented. To read or follow a conversation, a minimum number of words and sentences must be represented and related to past knowledge. It is common in tests of intelligence to ask individuals to recall number digits or words in their order of presentation or in reverse order.

Attention and Executive Control

Concentrating on what one is up to is not always easy. In normal conditions, everyone is surrounded by redundant information interfering with what we are up to. Focusing on a conversation in a public place is frequently hindered by all sorts of sounds in the environment or even thoughts uncontrollably popping into one's own mind. Planning to solve a problem may go astray because irrelevant ideas spoil assembling the sequence of actions required. Therefore, to serve their purpose, representational capacity, abstraction, and inference must be protected from interference. This is the function of attention and executive control (Posner and Rothbart, 2006).

The golden trio of this function is 'focus, inhibit, shift' (Zelazo, 2011; Zelazo et al., 2005). That is, when working on a problem, keep the goal in focus, inhibit turning to irrelevant

information even if attractive or interesting or initiating irrelevant action, and shift to other information or action, if the needs of the moment justify doing so. In current research on intelligence and cognition, attention and executive control are considered as manifestations of consciousness. That is, the ability to be aware of one's own self at any moment, of the flow of experience, and the contents of representational capacity, be it information from the environment, from past knowledge, or actions made or planned. Self-regulation is to a large extent possible because of this awareness and the processes that enable one to change its focus and content.

In tests of intelligence this ability is examined by tasks requiring the manipulation of information in working memory, such as when the examinee has to recall strings of letters and number digits in the right sequence and order. Also it is examined by tasks addressed to speed of visual processing which require to focus on one aspect of the stimulus and ignore another.

What Is General and What Is Specific in Intelligence?

Performance on any task at any moment is a composite of the processes specified above. That is, it involves knowledge, skills, and mental operations specific to the domain the task belongs to, it requires some kind of inference that would integrate knowledge, skills, and operations with each other and with the current goal, it is constrained by the representational capacity available, and it needs to be protected by irrelevant information or ideas for as long as needed. Nowadays, a dominant model of how to decompose what is involved in each intellectual task is the three-stratum model proposed by Carroll (1993). According to Carroll, the first stratum includes very narrow task- or medium-specific abilities, such as word knowledge, problem solving in mathematics, memory for words, specific information about the terms used in algebra. The second stratum contains broad abilities that organize a domain, such as storage and recall processes in working memory, general mathematical knowledge and processes in quantitative reasoning, knowledge and command of the rules of language. The third stratum is general intelligence or *g* itself. Carroll posits that *g* involves complex higher order reasoning, such as inductive and analogical inference.

In terms of the model shown in **Figure 1**, representational capacity, inference, and attention and executive control are all parts of general intelligence. The web of rules, heuristics, and information in each of the domains mentioned above belongs to the second stratum. More specific knowledge belongs to the third stratum.

A distinction that is often coming in the literature in different terminology is the distinction between processes that are used to grasp and deal with the new and unknown processes used to handle familiar situations. The most famous is the distinction proposed by Cattell and Horn (Cattell, 1963) between fluid and crystallized intelligence. Fluid intelligence refers to the use of reasoning to solve unfamiliar problems. Crystallized intelligence refers to the investment of fluid intelligence into knowledge that is culturally and practically useful. In the present terms, fluid intelligence would involve inference, representational capacity, and executive control and also mental operations in the various domains. Crystallized intelligence would involve the level of knowledge and beliefs in the various domains and also the various mental operations as automated and customized for use in various professional or cultural contexts.

In Sternberg's (1997, 2004) theory, analytic intelligence refers to mental processes of representation, interrelation and transformation of information; creative intelligence refers to the processes addressed to novelty and the creation of knowledge and operation possibly useful in the future; practical intelligence generates solutions relevant and useful in a given time and environment.

What Is Stable and What Is Changing in Intelligence?

The question can be answered from three different points of view: the architecture of intelligence, individual differences in concern to it, and the kind of concepts and problems that can be dealt with at different periods of life.

Stability and Change in the Architecture of Intelligence and Intellectual Attainment

The architecture of intelligence is considered to be generally stable. The four systems described above (i.e., the relational domains, representational capacity, inference, and consciousness) are present from very early in life and they continue to be so until the end. Also, these systems are present across cultures or social groups. However, the relations between the various systems may vary according to experience, developmental phase, and culture (Demetriou et al., 2005; Kazi et al., 2012; Sternberg, 2004).

Stability and Change in Individual Differences

The stability of individual differences in IQ is debated for a long time. Many textbooks of intelligence often report that the IQ is generally stable over time, especially between 5 and 6 years of age to middle age. This position reflects the fact that the correlations between IQ scores obtained at different ages in this span are generally high (between 0.5 and 0.7). In other words, the position of about 25–50% of individuals relative to their age group remains largely stable over age.

It is now well known that the IQ of many people may both increase or decrease and that these changes can even be associated with concomitant changes in the brain (Ramsden et al., 2011). Schooling is a factor that causes increases in IQ. Many studies suggest that there is an increase of something between 1 and 4 IQ points for each extra year of schooling (Ceci, 1991; Winship and Korenman, 1997). Gustafsson (2008) found that this effect came from changes in fluid intelligence. Moreover, in the later years, after the age of 60 fluid intelligence starts to decline, especially processing efficiency and representational capacity. However, crystallized intelligence does not decline until much later (Salthouse, 2000; Schaie, 1996).

Stability and Change in Development

The quality of intelligence changes extensively with age. In differential psychology this is reflected in the construct of

mental age. That is, it is recognized that different ages are typically associated with different cognitive accomplishments, although some individuals may progress faster than others thereby excelling their age mates. Overall, with age, representational capacity expands ascending from about one chunk of information at 1–2 years of age to about five to seven chunks at about 15–16 years of age (Pascual-Leone, 1970; Kazi et al., 2012). As a result, individuals can deal with increasingly more representations and more complex relations. Also mental processing becomes faster, better focused on goal, and increasingly controllable so that it can shift across concepts or actions, if needed. As a result, self-guidance, reflection, and self-awareness increase with age. Inference, although somehow always present, becomes increasingly analytic and complex. Thus, it moves from inductions based on similarity or probabilistic judgments based on the pattern of events in time and space to deductive reasoning (Kail, 1991; Demetriou et al., 2002; Zelazo et al., 2005).

Deductive reasoning gradually evolves from an automatic, heuristic, and context-dependent use of inference embedded into one's own language, in preschool (e.g., you can play with your friends only if you finish your homework) to analytic, domain-free inference enabling processing of abstract underlying logical relations. Gradually, the focus of inference shifts from the actual content to the necessary relations between propositions, if accepted as true (e.g., "Birds fly, elephants would fly if they were birds"). This decontextualization of inference starts in the early years of primary school and continues until early adulthood.

Also, deception as contrasted to truth, the real or actual as contrasted to the phenomenal (Wellman, 1990), and symbols as tokens of realities and ideas are more easily grasped and handled with age (DeLoache, 2000). The difficulty of problems in tests of intelligence varies along these dimensions. Therefore, the higher the IQ score on the test, the higher an individual performed on these dimensions of complexity, abstraction, logicality, and flexibility.

Why Do Individuals Differ in Intelligence?

Intelligence is normally distributed in the population. According to many, this is because intelligence is like any other physical characteristic, such as height (Jensen, 1998). This interpretation is usually associated with the assumption that intelligence is genetically determined and the genes associated with physical characteristics are normally distributed in the population. Obviously, in the case of intelligence, reference is made to genes that are associated with the formation, the development, and functioning of the brain, which is the 'physical organ' of intelligence, so to speak. In fact, there is no doubt that there is a line that goes from genes to brain to intelligence. For example, genes have been discovered that relate to the overall brain volume observed in individuals and overall brain volume is related to general intelligence (Deary, 2012; Hunt, 2011). Also, the Down syndrome, which is associated with low IQ (in the range of 50–70), is caused by a specific problem in a particular position of the DNA (there are three instead of two chromosomes at the 23rd position). This problem results into specific malformations in the brain. These malformations handicap information representation and processing in the brain, resulting in low mental achievements.

Individual differences genetically determined are inheritable to a large extent. There has been extensive research of the relations between heredity and individual differences in intelligence. This research includes siblings of systematically varying genetic and environmental similarity, such as twin siblings who grow in the family of their physical parents or in different families because they have been adopted by different parents. This research makes it clear that similarity in intellectual achievements increases with genetic similarity. Overall, about 50% of variability in intelligence is due to heredity. However, this varies with age. It is about 40% in childhood, 55% in adolescence, 60% in early adulthood, and 80% later in life (Deary, 2012; Hunt, 2011). It seems that, with age, people become more selective of their environment and they even actively shape it according to their own genetic propensities, leaving little room for influences that deviate from what they feel is suitable and manageable for them. Therefore, a large part of individual differences in intelligence are indeed due to heredity but the effect of environment is also very important, particularly in early childhood.

Culture, Gender, Social Class, and Intelligence

There is a long debate about differences between cultures in intelligence. The discussion about possible differences in intelligence was polarized in the twentieth century between two completely diverging epistemological positions. The first maintains that intelligence is a primary human characteristic and that, therefore, is the same across cultures. This view takes a second step, assuming that tests of intelligence developed in the West do measure this universal human characteristic. Therefore, differences in attainment, such as differences in average IQ attained by different ethnic or cultural groups, reflect differences in how much of this characteristic is possessed by each group. Research conducted from this perspective established a rather well-documented finding. That Western nations average about 100 IQ points, Eastern nations, such as Chinese, average about 105 IQ points, and African nations average about 85 IQ points (Lynn, 2008).

The second position maintains that intelligence is the expression of the worldview of a culture. Therefore, according to this position, it is not even possible to have a common measure of intelligence across cultures with different worldviews. Thus, it is just wrong to use a system of measurement capturing a particular worldview to compare different cultures; this would miss the essence of intelligence as developed and used in all other cultures. Nisbett (2003) suggests that cultures differ along important dimensions, such as the orientation to the individual as contrasted to the social group, the orientation of a holistic as contrasted to an analytical approach to problems, and the orientation to real-world functional organization of knowledge as contrasted to an abstract principled-based organization. Differences between cultures reflect differences in their history which, in turn, reflect long-term differences in needs and activity imposed by differences in the environment. For example, the individualist stance of the

West initiated in the geographically compartmentalized world of the Ancient Greeks and their ensuing localized administrative and political structures. This is contrasted to the open large spaces of the Chinese environment and their centralized administrative and political structures. According to this position, differences in IQ, such as those noted above, do not convey any meaningful information other than IQ tests capture an expression of intelligence that is tuned to the West, it favors the East, and it disfavors the South (Nisbett, 2003).

Cross-cultural research on intelligence and cognitive development has shown that dominant worldviews do shape how problems are approached and solved. Luria (1976), for example, showed that Asian peasants refuse to take the analytical stance and apply inference to solve a simple syllogistic reasoning problem: "All bears in the wood are black; Mischa met a bear today; what color is this bear?" These peasants responded that they could not know, provided that they did not see the bear themselves!

Many other studies showed that individuals in different cultures may be very proficient in solving locally relevant problems but very inept in dealing with standard school-like or test-like problems. Cole et al. (1971) showed that children in the Kpelle tribe in Africa use locally realistic and functional criteria for classification (robin is flying) rather than taxonomic criteria (robin is a kind of bird). The use of taxonomic criteria increased with schooling. Gladwin (1970) showed that the Puluwat in the South Pacific developed a sophisticated system of navigation that integrates information about the weather, the wind, the ocean currents, and the stars. This system enables them to navigate efficiently between islands. Carraher and colleagues showed that street children in Brazil, who make their living by selling various goods on the street, were more proficient in arithmetic calculations related to their business than in the standard school-based formal context. Moreover, they used strategies involving the mental manipulation of quantities in their street calculations (e.g., they produce global quantities which they then combine) rather than the manipulation of the symbols standing for the four arithmetic operations, as it is usual at school (Carraher et al., 1985).

This pattern of findings makes meaning in the context of the framework for intelligence presented here. That is, human intelligence is the same across human cultures. However, as an interface with the environment, intelligence is affected and constrained by cultural practices and knowledge and it is expressed through them. Thus, the command of general processes, such as executive control of representational capacity and the use of analytical inference, reflect the level of abstraction attained by a group. For example, the analytical stance is secondary in development and it needs to be cultivated and practiced systematically before it can be used spontaneously. At the same time, advanced knowledge and expertise reflect how general cognitive processes and abilities interact with a cognitive domain in cultural context. The success of Brazilian street children in their street version of mathematics does not indicate that these children have a different mind than their middle-class children in school. It only reflects that their transaction needs fostered the development of general inference and quantitative reasoning in ways that were enough for the task but of course were short of the needs of formal computation skills needed to deal with abstract arithmetic tasks at school. In the same way, the sophisticated navigation system of the Puluwat indicates that general inferential mechanisms, spatial thinking, and other domains are all integrated to generate expertise in a highly valued culture-relevant domain. Obviously, this system is very remote from the abstract electronically based navigation system used to navigate an airplane. However, they both organize space and time according to a complicated system of rules and knowledge that needs extended training and practice to be mastered. The systems outlined here are involved in both cases.

Different cultures may have long established institutions that may facilitate the relations and use of key systems of intelligence making them to excel in overall intellectual performance compared with other cultures. Schooling is probably the most influential of these institutions in fostering intelligence. It is reminded that each extra year of schooling causes increases in general intelligence in each student. In fact, this may even be related to the general increase of intelligence across generations. According to the so-called Flynn effect, general intelligence increases in the general population over the years. Flynn discovered that IQ increased by about 10 IQ points every 30 years since the beginning of the twentieth century (Flynn, 1987). Flynn (2009) ascribed this increase to two main factors. The increasing pressure for abstract thought that is required by our increasingly symbolic technological environment and the increasing expansion of education.

There may be other, more specific cultural institutions that may relate to the overall intellectual achievements of different cultures. A good example here is the learning of the logographic system of the Eastern cultures, such as Chinese or Japanese. Learning this system is extremely demanding on processing efficiency and working memory because children, from early in life, must become able to recognize and produce thousands of complicated visual patterns. There is evidence showing that Chinese children are faster in recognizing visual patterns and in their working memory capacity. This enhances general cognitive fluidity due to its pressures for symbol–meaning integration, generating a general advantage in information processing and problem solving (Demetriou et al., 2005; Kazi et al., 2012; McBride-Chang et al., 2011). It might be the case that the advantage of Eastern nations in general IQ noted above is related to this advantage.

There are factors within cultures that have been associated with differences in intelligence. The role of gender has been rather controversial in the literature. Overall, it is believed, more so in the past rather than at present, that males exceed females in mathematical and spatial reasoning and females exceed makes in verbal reasoning. These differences tend to diminish over the years and they have been associated with cultural differences in education and stance toward some activities related to the genders (Hunt, 2011).

The impact of social class is equally controversial. It is well documented that children growing in less privileged environments in concern to parental education and income have lower intellectual attainments (Hunt, 2011; Mackintosh, 1998). For many, this is the result of environmental factors related to the opportunities provided to children during their developmentally

critical years (Ceci and Williams, 1997). For others, this is the result of hereditary factors associated with selection of partners for mating and environmental contexts. According to this view, more intelligent individuals, who are generally more socially and professionally successful, have children with more intelligent individuals and less intelligent individuals have children with less intelligent individuals (Herrnstein and Murray, 1994). Thus, class differences are perpetuated for hereditary rather than social reasons. An interaction between these factors may be a more balanced interpretation of the differences (Hunt, 2011).

Can Intelligence be Changed by Education?

In this section we will outline a set of principles that education would have to adopt if it would directly and systematically both raise intelligence and facilitate knowledge acquisition. These principles derive from the four-system model summarized here and they are illustrated in **Figure 2** (see Demetriou, 2014; Demetriou et al., 2011; for a more detailed discussion of these principles and their implementation and also for other relevant references).

At any phase, education must lead the student to develop and refine the following cognitive skills: focus on relevant information; scan, compare, and choose according to goal; ignore irrelevant information; represent what is chosen and associate with extant knowledge; bind into models and rehearse if necessary; evaluate models in reference to evidence; reason by deduction to evaluate truth and validity of models and conclusions; prefer solutions that are better or nicer than extant solutions; estimate consistency with beliefs, extant theories, dominant views, and so on. Encode, symbolize, and embed into the system. Being aware of epistemological issues concerning the similarities and differences between disciplines is an important part of education for critical thinking and creative thinking.

These general educational goals must be tuned to the developmental possibilities and constraints of successive developmental phases. The general rules that may govern this tuning are as follows:

1. Educational priorities must capitalize on developmental milestones to make education feel relevant, appropriate, and useful for each phase of life. For example, education in infancy should be directed to practicing core operators to enhance infants' (1) understanding of the nature, behavior, and relations of objects and (2) their own relations with objects and other persons. Education at the preschool years must provide conditions for the knowing and handling of the multiplicity of representations, points of view, and their relation to reality. In the primary school years education must focus on revealing the connections between concepts and operations and facilitate children to see their own overt or mental actions vis-à-vis the concepts and operations. Education in early adolescence should focus on developing the "if … then" stance approach to problem solving, build epistemological awareness about the characteristics, possibilities, and limitations of different knowledge domains and sharpen the use of appropriate methods for different kinds of worlds or problems.

Figure 2 Function to be educated across the various systems and processes of the mind.

2. Intelligence may be improved by instruction addressed directly to the various aspects of working memory, attention, and executive control. Specifically education should aim to improve the ability to (1) monitor ongoing performance, (2) keep track of the flow of information and update it for as long as needed, (3) manage more than one task simultaneously (e.g., by alternating between blocks or types of information, if needed), (4) bind items according to type and time of presentation, and (5) inhibit irrelevant items. At the same time, organization and presentation rate of material to be learned must take into account the representational capacity and processing efficiency that is presently available to make learning possible and powerful at every phase. That is, the school must present concepts when the representational potential of individuals meets the representational demands of concepts to be taught.
3. Education must practice, consolidate, and build models for mental operations that are specific to different domains. For example, it would be useful for classificatory thought to have a template for classification and categorical relations between concepts, such as tree diagrams. Also, a model of the basic relations of causality (i.e., necessary and sufficient, necessary and not sufficient, neither necessary nor sufficient, and incompatible) would be helpful in directing the student how to manipulate and grasp cause–effect relations. Students must be induced into theme- or concept-appropriate models of the fields of interest, such as gravity, inheritance, motion. Teaching must lead the students to understand where and why these models are better than their own respective concepts or models.
4. Special attention should be given to decontextualization of inference from content and context. For example, at preschool, children may be trained to realize that the information in the premises is connected by inference. At primary school, directed comparisons across different types of arguments would enable children to differentiate form from content and understand that logic constrains inference. In adolescence education may focus on the formal aspects of different types of arguments.
5. Problem solving involves all of the processes above and it should be demonstrated and practiced as such. Students must be educated in foresight, anticipation, and formulation of alternative plans for problems. Envisaging, comparing, substantiating, debating, and choosing among alternative models, if properly directed, would make the student able to become sensitive to the role of evidence and logical and conceptual substantiation for alternative models. Moreover, with age, knowledge and context are increasingly important for successful, acceptable, and creative problem solving.
6. Finally, students must know themselves: the organization and functioning of their own mind, their own strengths and weakness, and they must be able to adjust their actions and learning accordingly. Each process has a role and each solution has a value, given the context in which it was produced and in which it will be used. For example, Zelazo (2011) suggests that mindfulness training since preschool enhances self-monitoring skills which in turn enhance executive control thereby improving learning. At primary school, education must focus on building awareness of the differences between mental functions and of their differential impact on learning. Adolescents may be guided to grasp the differences between formal disciplines, such as mathematics, and empirical disciplines, such as physics, in knowledge construction. This would enable them to evaluate the differences between the knowledge produced by these disciplines.

Conclusions

In conclusion, the human mind is a complex system of general and specialized processes. "The relations between the general and the specialized processes are complex and bi-directional. On the one hand, general processes set the limits for the construction, operation, and development of the domain-specific systems. On the other hand, specialized processes provide the frame and raw material for the functioning of general processes" (Demetriou et al., 2010: pp. 34–35). The development of each and of their relations is long and dynamic, and it occurs on several fronts at the same time, and it can be described in terms of complexity, abstraction, analytical attitude, long-term planning, and ingenuity in organizing and using knowledge for the sake of personal and collective good and development. This always takes place in particular culture at a particular time. Therefore, in Sternberg's words, "Intelligence cannot be fully or even meaningfully understood outside its cultural context" (2004: p. 325).

Intelligence, Prior Knowledge, and Learning

Abstract

Intelligence test scores can account for achievement differences in many content areas to a considerable extent. An individual's intelligence quotient results from complex interactions between genes and environmental stimulation, foremost schooling. The amount of variance in intelligence to be explained by genes is the higher the more successful a society is in providing cognitively stimulating environments for everybody. Intelligence can be understood as a start-up resource of information processing which has to be invested in knowledge in order to enable competencies in a domain. Teacher's professional competencies have a major impact on how learners exploit their intelligence for learning particular subjects.

Intelligence: A Valid Predictor of Achievement Differences

Individuals with similar cultural, social, and educational backgrounds differ from one another in the time they need to process certain information, in their ability to understand complex ideas, in the efficiency with which they can deal with novel, transfer demanding tasks, and in the learning outcome that results from attending certain instructional environments. The construct of psychometric intelligence attempts to clarify what is behind such achievement variations that cannot be explained by differences in learning environments or in amount of practice.

Measuring Intelligence

About a century ago Alfred, Binet constructed problems designed to determine whether children who did not meet certain school requirements suffered from mental retardation or from behavioral disturbances. Since then many psychologists have been quite successful in developing reliable verbal and nonverbal intelligence tests for children and adults. Intelligence tests contain items composed of verbal, numerical, and pictorial material, and they require various mental operations, among them inductive and deductive reasoning, pattern recognition, and memorization. So-called speed tests contain items that are comparably easy for everybody; individual differences in the numbers of correctly solved problems only occur because of time limitations. In power tests, the items are ordered according to their difficulty, and limits in intelligence become apparent if people do not solve all problems despite having sufficient time. The distribution of achievement scores in all intelligence test scales follows the bell curve (normal distribution). This reflects the fact that the majority of people resemble each other quite a lot with respect to their cognitive capabilities, and only a few people show extraordinarily low or high competencies. Normal distribution is the statistical prerequisite for measuring intelligence on interval level by indicating deviations from the mean score. To determine the intelligence quotient (IQ), test scores are converted to a scale in which by convention the mean is 100 and the standard deviation is 15. The reliability of IQ tests, revealed either by correlation coefficients based on repeated measurement or by figuring out internal consistency, is between 0.80 and 0.90, which is higher than for most other psychometric measures. Nonetheless, a reliability lower than 1.0 only allows us to interpret a range rather than a single value. For example, if a person's tested IQ is 110, and if the reliability of the test is 0.90, the IQ of this person is between 101 and 119 with a probability of 95%. A test reliability of 0.80 reveals a range of 97–123.

Despite broad variations in the content and the form of presentation of intelligence test items, all tests have in common that they do not presuppose knowledge that can only be acquired in particular learning environments not accessible to everybody. Moreover, differences in test scores within a group only reflect differences in intelligence between these persons if all of them have had access to comparable learning environments. In other words, each member of the group must have had, in principle, the opportunity to acquire the knowledge necessary to solve the problems. Intelligence test scores can be raised considerably by practicing the respective types of items, while individual differences do not disappear but rather remain quite stable at a higher level. The Flynn effect, named for its discoverer, is the observation that modernization of a nation goes along with massive IQ gains over time. In the meantime, many highly developed countries have reached an asymptote, while nations where modernization began later still gain around three IQ points per decade. Reasons for the Flynn effect are manifold and still under debate, but it is undisputed that better schooling as well as widespread exposure to tasks which resemble intelligence test items in various media are major causes.

Individual differences in intelligence test scores between persons can only be interpreted as differences in general cognitive resources if similar amounts of practice can be presupposed. Attempts to construct so-called culture-free or culture-fair tests, which were supposed to be unaffected by prior experience, have failed because it turns out that different cultures are not prepared in the same way even for dealing with nonverbal material and mental operations that are not part of institutional schooling. Although some studies reveal ethnic differences in mean IQ, hitherto there is no convincing

evidence that these differences are genetically affected. There is rather overwhelming evidence that all ethnic groups gain IQ points as a consequence of better schooling. Within a fairly homogenous cultural context, intelligence can be considered as a personality trait mainly for two reasons. First, performance on intelligence items that are based on different contents and mental operations show significant correlations. For instance, correlations between tests on inductive reasoning with pictorial material and with verbal material are around 0.50, and correlations between tests that measure basic visual–spatial competencies such as mental rotation and tests of verbal fluency are about 0.30. In numerous studies run all over the world, multivariate statistical methods such as factor analysis have revealed that a single factor, called factor *g*, can account for 40–50% of the variance in IQ test batteries composed of various scales covering a range of content knowledge and mental operations. Second, longitudinal studies have revealed that IQ is a fairly stable measure across the life span. Long-term stability of IQ for adolescents and adults comes close to the reliability of the tests, as, among others, a once-in-a-century study from Scotland has shown (Deary, 2012). Even cognitive measures of attention gained in early childhood reveal long-term correlations are around 0.50 for both verbal and nonverbal tests. Overall, intelligence test scores predict academic performance fairly well: the correlations between IQ and grades in school and university are about 0.50. The correlations between intelligence test scores and measures of outside-school success such as income or professional status are lower but still significant. That intelligence cannot account for a larger amount of achievement variation is not at all surprising, given the importance of numerous other factors, among them social background, motivation, and effort. A longitudinal study by Duckworth et al. (2011) revealed that standardized achievement test scores were stronger related to intelligence than to motivational factors, while grades determined by teachers were determined more by factors like self-control than by intelligence.

Given that verbal and nonverbal intelligence tests are good predictors of how well an individual will succeed in school and university, they are quite helpful for making recommendations for different educational trajectories. They allow educators to identify children who cannot be expected to gain sufficiently from standard schooling and therefore need extra support adapted to their special needs, or children who might benefit from an advanced learning environment. The validity of intelligence tests can be further increased by the dynamic testing approach (Sternberg and Grigorenko, 2002), which means that all test-takers practice the items in several trials by getting feedback and thinking hints so that individual differences in familiarity with tests are compensated for. Particularly for children from disadvantageous social environments, learning tests are a more reliable and valid measures of intelligence than conventional IQ tests. Attempts to extend the construct of intelligence by including social and emotional competencies as well as striving for success are controversial because the theoretical background of these concepts is still vague, and, more importantly, because the tests designed to measure these aspects do not meet the strong diagnostic criteria that have been established in psychometric research (Neubauer and Freudenthaler, 2005).

What Is Behind Intelligence: Factor *g*, Working Memory, and Specific Abilities

What cognitive capabilities are behind factor *g* is still under debate, although in the past decade major insights could be seen to emerge. This is also due to the fact that much has been learned about the neural underpinnings of human intelligence. The substantial negative correlations between IQ and reaction times in solving simple problems that had been found in numerous studies can now be interpreted in the light of brain imaging research. A constant finding is that more intelligent individuals show less brain activation (measured by electroencephalography (EEG) or functional magnetic resonance imaging (fMRI)) when completing intelligence test items. The more intelligent a person is, the less neural resources he or she needs for solving the problem (Neubauer and Fink, 2009). Particular progress has been made in localizing the brain areas which indicate differences in intelligence: the prefrontal cortex, an area which plays a major role in dealing with complex and novel problems as well as in working memory functions. Considerable progress has been made in bringing together research on working memory and intelligence (Oberauer et al., 2008). Working memory is understood as a central cognitive function of human beings which is responsible for temporarily maintaining and manipulating knowledge during cognitive activity. Working memory functions are measured by tasks that require the goal-oriented active monitoring of incoming information or reactions under interfering and distracting conditions. Performance variations in these tasks have been found to be highly related (average correlations of 0.70 are reported) to differences in intelligence test scores. Psychologists agree that although there is more to IQ than working memory functions, the latter should be regarded as an explanatory construct for reasoning abilities.

Although factor *g* can be extracted from different intelligence tests, many correlations between intelligence subtests, though significant, are low, indicating the involvement of independent mental resources. Even between tests on inductive reasoning which are based on different forms of representation (i.e., pictures, numbers, words), only medium correlations are revealed, suggesting that cognitive processes are to a large extent guided by specific verbal, visual–spatial, or numerical abilities, among others. Since the 1960s, concerted attempts have been made to integrate general and specific abilities into broader theories of intelligence in a hierarchical model which is now known as the Cattell–Horn–Carroll theory, which has been recently discussed in light of modern IQ tests by Kaufman (2009). Psychologists now agree that the abilities which contribute to intelligence tests scores are best classified on three levels. Narrow abilities on level one either refer to speed of sensory processes or specific competencies acquired through learning (e.g., reading skills). The broad abilities on level two go on from the distinction between fluid intelligence (Gf) and crystallized intelligence (Gc). Gf mainly describes logical reasoning, measured by content-poor nonverbal tests, and Gc, which is particularly revealed in content-rich verbal tests, represents the accumulation of reading and writing skills as well as higher-order knowledge over the life span of an individual. Level three describes

a unified component of cognitive competencies which corresponds to the general factor.

The distinction between Gf and Gc is important in light of age-related changes of intelligence. While both kinds of intelligence are closely interrelated in childhood, from the age of about 25 years on, however, Gf and Gc take different developmental trajectories. While Gf starts to decrease at the age of 25, first slightly and from about 50 years on more quickly, Gc is unaffected by age and even has good chances to increase until the age of around 70. It is worth noticing that because of the large individual differences, the given age information is only a rough estimation. Developmental changes also occur with respect to the structure of intelligence. The prominence of Gf decreases during childhood while Gc as a function of repeated enlargement and rearrangement of knowledge becomes more useful.

Intelligence as the Result of Gene–Environment Interactions

The question of heritability of intelligence can still cause quite a stir in the broader public. In science, however, the controversy on whether genes have an impact on the development of intelligence is a thing of the past. To make a long story short, it is no longer the question of nature *versus* nurture but nature via nurture (Ridley, 2003). Every aspect of human behavior is embodied in genes but it is the environment which triggers gene expression. Particularly the comparison between identical and fraternal twins shed light on the impact of genes on intelligence. The correlation between the intelligence test scores of raise-together identical twins almost ties up with the reliability coefficient of the respective test. At the same time, the correlation between fraternal twins rarely exceeds the correlation found between regular siblings, although the latter group due to their age differences had been sharing less experience than twins. Other studies revealed that the IQ of young adults who had been adopted shortly after birth was more similar to their biological than to their adoptive parents.

Altogether, twin and adoption studies suggest that 50–80% of the IQ variation is due to genetic differences. This relatively large range of percentage across different studies is due to the population dependence of heritability. It is namely the case that the amount of variance in intelligence test scores explained by genes is higher as more members in a society have access to school education, health care, and sufficient nutrition. Several studies revealed lower heritability of intelligence for children raised in lower socioeconomic status (SES) families (Turkheimer et al., 2003). It turned out that lower SES fraternal twins resembled each other more than higher SES ones, indicating a stronger impact of shared environment under the former condition. Or, in other words, because of the less stimulating environment in lower SES families, the expression of genes involved in the development of intelligence is liable to be hampered.

The complex interaction between genes and environment is also founded on the fact that heritability of intelligence increases during the life span. To understand this very well-established finding, one has to realize that societies which provide access to a broad variety of cognitive activities in professional as well as in private life enable adults more than children to actively select special environments which fit their genes. People who have found their niche can perfect their competencies by deliberate learning. Although, however, it is beyond any shadow of doubt that in developed societies, genes can explain a huge amount of IQ differences, the search for the genes responsible for the expression of cognitive capabilities has not at all met with much success, despite the money and effort invested in human genome projects. Given, however, that even for height less than 20% of the variance can be traced back to already identified genes, it is far from surprising that it is almost impossible to track down the genes that are involved in intelligence (Deary, 2012). It is entirely plausible that very large numbers of genes are spread out across the entire genome and have their share, and moreover these genes seem to interact in very complicated ways with each other as well as with environmental cues. In the foreseeable future, biologists will not be able to predict a baby's cognitive capabilities from his or her DNA. Personalized education, which means that a child gets the education that fits his or her genome, is nothing but a pipe dream. What can, however, be said for sure is that in societies which provide a cognitively stimulating environment for everybody, intelligence differences will not decrease but rather increase on a high level.

Genes, however, not only indirectly guide learning and knowledge acquisition via general and specific abilities. There is rather growing evidence that during evolution, the human mental architecture has been equipped with quite specific knowledge structures, for instance, about visual or auditory patterns, numbers and magnitudes, physical objects, language use, and social situations. Such knowledge structures, typically labeled as core knowledge or privileged knowledge (Spelke and Kinzler, 2007), allow human beings appropriate cognitive and behavioral functioning from the very beginning almost without effort. Such kind of fast learning sharply contrasts with the huge difficulties human beings may encounter when it comes to learning at school. For better understanding the obstacles and often even the severe difficulties that can occur when youngsters are supposed to acquire academic skills and competencies as there are reading, writing, or mathematical and scientific reasoning, one has to take into consideration the evolution of these fields in a cultural context during the past millenniums if not centuries or even decades. A today's child, equipped with a DNA comparable to the one of a stone-age person, is expected to acquire knowledge within few years which took mankind millenniums to develop. The core knowledge human beings have been equipped with during evolution can be the starting point for building more advanced knowledge structures in different domains. In the case of mathematics, it is entirely plausible that nature has equipped human beings with intuitive number knowledge and sensitivity for magnitude. As a consequence, to the best of our knowledge, all cultures have numbers words, even illiterate ones. However, having specific symbols for numbers is even not common among all cultures with script. The Arabic place value number system, which is now common in most parts of the world, was only developed a few hundred years ago. Only after the number '0' had made its way from India via the Arabic countries to Europe that the preconditions for developing our decimal system were given. It was the Arabic number system which opened up the pathway to academic mathematics.

Cultural transformations based on invented symbol systems were the key to advanced mathematics. Central content areas in mathematics curricula of high schools, such as calculus, were only developed less than three centuries ago. What makes school a real challenge is the fact that within a few years young people have to acquire knowledge which has been developed over centuries by genius minds with tremendous effort. While intuitive quantification seems to be a universal cognitive resource almost unaffected by differences in intelligence, correlations of $r = 0.50$ and higher are found between IQ and achievement in mathematics. Discovering principles that underlie the relationships between numbers and understanding how some of these principles can be described in verbal, numerical, and graphical representations required general cognitive resources. This leads to the more general question of how domain-specific knowledge has to be represented in order to allow reasoning and drawing inferences. In the past decades, cognitive scientists have developed theories of knowledge representation which enable higher-order reasoning and academic competencies. Moreover, educational science has worked our frameworks for learning environments that can foster the acquisition of usable knowledge.

Knowledge Construction

Intelligence can be understood as a start-up cognitive resource which has to be invested in the construction of knowledge in order to enable behavioral and cognitive functioning, including problems solving and decision making. How well such activities work out particularly depends on the quality of knowledge representations in the particular content domain. Knowledge has a multifacet nature, among them knowledge about facts or abstract concepts, about how to efficiently solve routine problems, and knowledge about more generally applicable learning strategies. These different facets of knowledge all interact in contributing to a person's competence, and they can differ in their functional characteristics. Elements of knowledge can be isolated or interrelated, context-bound or context-general, abstract or concrete, implicit or conscious, inert or accessible with different degrees. Just having a high accumulation of factual knowledge in a domain is usually not at all enough for cognitive and behavioral functioning. To characterize this situation, the term 'inert knowledge' has been invented. An example of inert knowledge is vocabulary of a foreign language which has been learned and stored in memory in a dictionary style, but cannot be retrieved during natural communication.

Cognitive scientists have agreed on distinguishing between declarative (knowing that) and procedural (knowing how) knowledge, a differentiation that can be applied to a broad variety of subject areas. Declarative knowledge can be communicated because it is represented on the basis of symbol systems (language, script, mathematical, or visual–spatial representations). Declarative knowledge can be applied to concrete instances and facts, or to general and abstract knowledge of the core principles and their interrelations in a domain. It is assumed to be stored mentally in some form of relational representation, for example, schemas or semantic networks which allow for its flexible transformation through processes of inference and elaboration. Declarative knowledge is therefore not bound to specific problem types and it is, in principle, transferable to other problems.

Procedural knowledge, in contrast to declarative knowledge, is usually seen as knowledge of operators and the conditions under which they can be applied to reach certain goals. It can be automated to different degrees, depending on the extent of practice. Automated procedural knowledge can be used with minimal conscious attention and few cognitive resources. This efficiency, however, has the drawback of inflexibility. Because automated knowledge is only partly open to conscious inspection, it can hardly be verbalized or transformed by higher mental processes. As a consequence, it is often tied to specific problem types. Both kinds of knowledge are involved in reasoning and problem solving in any domain, but they are acquired in different pathways. Procedural knowledge results from practice and repetition. The more often we conduct an action in the correct way, the less attention and control will be needed.

Declarative knowledge can be subdivided into factual and conceptual knowledge. While facts can be acquired by rote-learning, conceptual knowledge, in contrast, results from conscious elaboration and reasoning with progressively focusing on defining rather than on characteristic features. This transition was studied for a great variety of concepts from different domains. Younger children, for instance, associate the concept of 'parents' with 'caring for young children,' whereas older children focus on 'having offspring.' Younger children in elementary school will agree that a pile of rice has weight, but deny that an individual grain of rice has weight as well. This seemingly implausible answer turns out to be highly plausible if one realizes that for younger children, 'weight' and 'being heavy' are still equivalent. When being asked whether a grain of rice has weight if it is put on the back of an ant, their answer is yes with deep conviction (for an overview, see Stern, 2005).

Research on learning science and mathematics has shed light on numerous differences in conceptual understanding between experts and novices. This is a particular challenge for schools in general and for teachers in particular. Particularly in subjects like science and mathematics, many teachers are disappointed about their student's scant learning gains despite the effort they put into preparing and structuring the lessons. They strictly keep to a logical sequence, and they present very clear and precise definitions, preferably based on mathematical formulas. As long as tests require students to reproduce definitions and to figure out quantitative information, performance often seems satisfactory. However, a serious lack of conceptual understanding remains, as even the most intelligent students often cannot transfer the insights they should have gained to problems that differ from those dealt with in the classroom. What has gone wrong? Often teachers hold the 'direct transmission' view of learning (Staub and Stern, 2002), according to which successful classroom practice is seen as teachers' providing of information that students memorize and retell. Such learning environments, however, may, at best, help students accumulate facts or acquire simple skills but will not support them in building up the conceptual knowledge they need to model new and complex situations, as required in science and mathematics.

The main barrier that keeps students from learning science and mathematics is not so much what they lack, but what they

have – namely, naïve scientific knowledge that often works well in everyday life but largely differs from and even contradicts scientific explanations. Thus, to support students' learning, teachers must diagnose students' initial understanding of the content at hand. Knowledge not conforming to scientific views should not be dismissed as the sad result of deficiencies in previous instruction but, rather, be recognized as an inevitable step in learning. Effective teaching requires presenting students with questions and problems that stimulate processes of knowledge reorganization and thereby help them overcome their bounded or deficient beliefs. Thanks to concerted efforts in educational research, we nowadays know very well that it is the cognitively stimulating classroom environment created by the teachers which is crucial for meaningful learning at all achievement levels. In John Hattie's book *Visible Learning*, more than 800 meta-analyses dealing with factors that might influence school-related achievement were analyzed and synthesized. Obviously accessible factors like class size, methods of instruction, or use of computers were of negligible impact. What counts for student's meaningful learning, however, are teachers who are able to transform student's errors into learning opportunities by providing tasks and tools which make the difference in light of what the students already understand and misunderstand. By presenting their students with challenging but solvable tasks and problems, competent teachers support the construction of a knowledge base where abstract concepts, facts, and procedures are integrated and enable mutual activation.

Prior Knowledge: The Best Predictor of Learning Outcome but Not a Substitute for Intelligence

When entering new learning settings, students often differ from one another. Domain-specific knowledge and intelligence have been identified as the two major sources of difference. Research on cognitive development suggests that variations in prior domain-specific knowledge can often better account for achievement differences between younger and older children than general cognitive capabilities. Moreover, longitudinal studies, such as the Munich Longitudinal Study LOGIC, revealed that within-age level achievement, differences in core elementary school subjects are to a remarkable extent determined by domain-specific prior knowledge obtained in the preschool years. Early numerical competencies could account for achievement variations in mathematics after partialing out general intelligence, and early indicators of letter identification and phonological awareness predicted later performance in reading and writing (Schneider and Bullock, 2009). The reported results are important because they show that at least in complex knowledge domains a high IQ cannot compensate for a lack of prior knowledge, and moreover, that there is no direct connection between intelligence and achievement in content domains based on rich specific knowledge. However, regression analyses based on longitudinal studies reveal that the confounded variance of prior knowledge and intelligence predicts differences in learning outcome better than each single variable. If more intelligent children are placed in stimulating learning environments, they will acquire usable knowledge which will increase their lead.

There is, however, overwhelming evidence for the pivotal role of prior knowledge for further learning and advanced performance. Studies in different areas, among the mathematics, science, and chess, have revealed much better outcomes for persons with high prior knowledge levels (experts) and somewhat lower IQ than for persons with little prior knowledge (novices) and high IQ (Grabner et al., 2007). Note, it were novices and not laypersons who were considered in these studies. In contrast to laypersons novices possess the necessary domain-specific knowledge in terms of rules and core concepts but differ from experts in their lack of practice.

For individuals who grow up in a cognitively stimulating environment, prior knowledge and intelligence are to a certain extent inextricably linked with each other. Intelligence may guide the selection of learning environments and thereby determine the acquisition of prior knowledge. A person with a low IQ will hardly follow courses on theoretical physics even if he or she is credited with extra time. Moreover, intelligence may affect the number of content areas in which a person is able to acquire a profound amount of prior knowledge. This view has been clearly confirmed by the Study of Mathematically Precocious Youth, in which individuals were identified on the basis of very high reasoning abilities before the age of 13. Thirty-five years later, these individuals achieved occupational success comparable to that of individuals attending world-class mathematics, science, and engineering graduate training programs. A remarkable result was that the ratio of very successful people in the upper quarter of this highly selected sample (percentile >99) was higher than in the lower quarter (Lubinski and Benbow, 2006).

Intelligence and Learning: Educational Implications

Comparisons between schooled and unschooled groups reveal a strong effect of education on intelligence test scores even on nonverbal tests. Only by systematic education can individuals' intelligence emerge and approach an optimum. However, given that a basic level of education has been encountered, schooling in general and special training programs in particular increase intelligence only very modestly, if at all. IQ differences remain quite stable over time in groups who have been attending stimulating learning settings. Education highlights individual differences in intelligence rather than compensating for them. Broad variance in intelligence is a challenge for designing educational environments. The question arises whether learners of different intelligence levels gain more if they are assigned to different learning environments. On a first glance, it sounds plausible that less intelligent students gain more from structured than from open instruction, while more intelligent learners show the reverse pattern. This was the hypothesis when so-called aptitude–treatment interactions were investigated. However, most studies have failed to reveal interactions between intelligence and educational treatment, some of them probably because they lacked the statistical power necessary for revealing interaction effects (Hattie, 2009). In general, when assigning learners to different learning treatments according to their intelligence, one must remember that IQ follows the normal distribution. This means that 68% of the people in a population do not differ by more than one standard deviation

in either direction from the mean – they are quite similar. Therefore, assigning an unbiased group of learners to two different learning environments by median split of IQ scores is basically problematic.

While attempts to reveal aptitude–treatment interactions have not met with much success with intelligence as indicator for aptitude, it has been shown in many contexts that learners gain from different inputs depending on their prior knowledge. For instances, for areas in science and technology, it has been shown that visual–spatial representations do help novices in understanding complex situations while they are either needless or distracting for experts (Mayer, 2009). Similar results have been shown for including means of focused processing, as there are self-explanations or metacognitive questions. While they help novices to develop a deeper understanding of a subject matter by becoming aware of their misunderstandings and wrong conclusions (Atkinson and Renkl, 2007), experts would be unnecessarily detained by such aids. Such results are not surprising because when being presented with a problem, experts and novices differ in whether they already can fall back on established procedural and conceptual knowledge structures or whether they first have to build them up. Therefore there are better reasons to assign learners to different treatments based on their prior domain-specific knowledge than based on their intelligence. Given the relationship between intelligence and efficiency in learning and information processing, a higher IQ facilitates the exploitation of learning environments, leading to the acquisition of knowledge that is broad as well as deep enough to be prepared for mastering as yet unknown demands of the future. As a consequence, the knowledge gap between more and less intelligent students will increase in the course of time. More intelligent learners who have invested their intelligence in the construction of broad and deep knowledge will be prepared for entering demanding and abstract subjects which will remain closed for those who started under less advantageous conditions. Providing different educational tracks for learners with a vocational focus and for those who are qualified for an academic path is part of the educational system of most countries. There are, however, remarkable differences concerning the age of the students at which the separation starts. While this is around 15 in many countries, in Germany and Austria, for instance, the separation starts as early as 10 years. Meta-analyses, as they are reported by Hattie (2009), revealed almost no impact of ability grouping on student's achievement growth. It rather seems to be the case that professional teachers, who are aware of their student's thinking and knowing and who provide meaningful experience in light of this knowledge, are able to boost different student's potential.

Intensification and Specialization, Archaeology of

Kathleen D Morrison, University of Chicago, Chicago, IL, USA

Abstract

Changes in the organization of production are associated with significant historical transitions such as the development of food production, settlement aggregation and sedentism, the institutionalization of social and other inequalities, occupational specialization, urbanization, exchange, the production of surpluses, and the development of markets. Understanding production in terms of its constituent processes has thus been critical. Two of these processes, the intensification and specialization of production, lie at the heart of many of these transitions and are used to characterize the level of effort, productivity, land and labor use, and degree of skill in agricultural production and craft or artifact production.

Many of the major historical transitions studied by archaeologists – the development of agriculture, urbanism, institutionalized inequality, markets, and processes of imperial incorporation, colonialism, and political collapse – consist of, or are accompanied by, significant changes in the organization of production. Studies of intensification and specialization build on archaeological approaches to production, and must be understood in light of this construct, which differs significantly from its use in economics. Both intensification (usually examined in terms of agriculture) and specialization (generally studied in terms of craft production) are often viewed as pivotal to the development of institutionalized inequality and complex polities, although there is increasing recognition that specialized production has at times existed even in minimally stratified societies. Beyond the potential significance of intensification and specialization for the development of social complexity, both processes are also implicated in equally fundamental changes in human demography, labor organization, the development of social and gender identities, and changes in regional landscapes and floral and faunal assemblages. Recent developments in the archaeology of intensification and specialization tend to stress process over cause, highlight temporal and spatial diversity, and explore the consequences of productive organization for differently situated social actors, rather than classify productive forms on an evolutionary continuum.

The Archaeology of Production

Archaeological concepts of production are typically situated in the anthropological perspective that productive activities are embedded in larger cultural and social systems. Production – the creating, constructing, and tending of artifacts, structures, human-modified plants and animals, even entire landscapes – is a fundamental focus of the study of the archaeological record. Production, as one dimension of human economy, is both responsive to and constitutive of other domains such as processing, distribution, and consumption. This perspective is a legacy of the formalist–substantivist debate in anthropology, which centered around whether nonindustrial economies could be understood in the same terms as industrial capitalism (the formalist position), or whether the economies of nonindustrial societies typically studied by anthropologists were, in Polanyi's (1957) words, more fundamentally 'embedded and enmeshed' in social institutions. However, this picture is complicated by the existence of branches of archaeological thinking, which draw on economistic approaches or on those approaches as modified by ecology and evolution.

Research has not focused evenly on all arenas of production. Although agriculture and animal husbandry constitute important areas of research, there is a longer history of emphasis on durable goods or artifacts, objects made or modified by humans. Artifact manufacture is often termed craft production. While changes in the organization of craft production are generally conceived in terms of specialization, food production is more often viewed in terms of intensification. Part of this divergence may relate to the different kinds of information available about each arena of production. Students of craft production typically work with artifacts themselves and with evidence from production locales such as kilns, workshops, and even dumps. Food production research does involve products such as seeds and animal bones, or objects used in food preparation such as ceramics and ground stone, but these are often conceived as objects of consumption, with production studies focused primarily on locales of production such as fields.

Intensification

Archaeological studies of intensification have focused primarily on agriculture. In some sense, the historical trajectory of agricultural change can be viewed as a long, although variable, history of productive intensification, concomitant with the rise in global population, its clustered distribution on the planet, and the entrenchment of economic and social inequality.

The Concept of Intensification

The difference between intensification and simple increase is analogous to the difference between concentration and amount. Intensification of production refers to attempts to increase the concentration of production, or productive output per unit of land, labor, or some other fixed quantity.

The focus on production effort in this definition highlights the salience of input, allowing failed efforts to increase productivity to be included in studies of intensification. In archaeology, the variable held constant almost always refers to land in reference to agriculture (getting more from a given area), and labor in reference to craft production (increasing efficiency of production). Situations in which both land and labor are held constant while capital inputs are increased, as in industrialized agriculture, are less often discussed. An important exception to this is the concept of 'landesque capital' intensification. First advanced by Blaikie and Brookfield (1987), landesque capital highlights the role of farmers in creating enduring landscape modifications such as terraces that allow for more intensive forms of production over the course of many human generations without a sustained increase in effort (Widgren, 2007).

History of Approaches to Intensification

The model of intensification set forth by economist Ester Boserup (1965) has been the most influential formulation of the problem, and was widely adopted in archaeology (e.g., Cohen, 1977). Boserup's model was parsimonious, general, and comprehensive; however, like other unilineal models of cultural evolution, it greatly generalizes and simplifies this complex process. Boserup's view of population pressure as an independent variable driving intensification inverted the earlier Malthusian formulation. While Malthus saw arable land as limiting increases in production, Boserup optimistically asserted that constantly increasing population (an assumption shared with Malthus) acted as a motor, driving technological changes in land use along an extensive–intensive continuum.

The most contested aspect of Boserup's model was the causal efficacy of population pressure, a view resting on several related assumptions. First, producers are assumed to exert the minimum effort required to meet their needs (the law of least effort). Thus, the most labor-extensive regime possible will always be employed. Second, Boserup argued that there are diminishing marginal returns to labor (declining efficiency) with increasingly intensive forms of production. The disadvantages of intensive agriculture – increased labor inputs and declining efficiency of that labor – ensure, for Boserup, that more intensive forms of production will be adopted only when strictly necessary. These assumptions have been criticized on empirical grounds, as has the prime-mover status of population pressure. There is now a vast literature considering such causal factors as population density and distribution; sedentism; market-driven, prestige-driven, or politically driven demands for produce; risk; climate change; and many others (reviewed by Morrison, 1994). Contemporary approaches to intensification tend to stress multiple and cascading causes, which may be locally contextual and historically contingent (e.g., Kirch, 1994).

Consequences of Intensification

In a proximate sense, the most common consequence of intensification is increased productivity. Equally significant, however, are less proximate consequences, such as the restructuring of human labor, possibilities for differentiation of nonfood production, and the support of nonproducers. It is in this sense that intensification has been seen as underwriting social and political complexity, by which archaeologists generally mean the existence of institutionalized inequality and/or the presence of complex polities such as states or chiefdoms. Historically, intensified food production has also had dramatic ecological consequences, leading to landscape modification on a large scale, the worldwide movement of plant and animal taxa, and support for artifactual landscapes such as cities (see papers in Thurston and Fisher, 2007). Indeed, the Industrial Revolution may be seen as a case of the intensification of specialized forms of production, a process that has had significant ecological as well as social and economic consequences.

Methodological Issues in Intensification Studies

The study of intensification poses serious methodological challenges. The investigation of past agriculture, in particular, is difficult because of its large spatial scale and ephemeral material remains. For this reason, archaeologists consider numerous indicators of land use, including agricultural implements, historical documents, settlement distributions, types and distributions of agricultural facilities, paleo diet indicators, and botanical remains. Identifying intensification in the archaeological record depends on the definition adopted; views that stress output require some measures of productive success, a difficult requirement for archaeology, where agricultural productivity can rarely be quantified. Output-based models are more popular in craft production studies, where such measures may be more reasonably inferred. Production effort is usually postulated on the basis of inferences about the overall form of production, using clues such as technological forms, products, or cultigens with special productive requirements, as well as knowledge of specific environmental conditions.

The Future of Intensification Studies

Three promising trends in the archaeology of intensification may be identified. The first is increased attention to the process of intensification itself, a process incorporating a great degree of variability. Kaiser and Voytek (1983), for example, divide intensification into three components: specialization, diversification, and intensification proper. These involve changes in the amount and organization of labor and its application through technology, and require measurement of multiple variables. The second trend is increased attention to actual historical trajectories of change and the variable paths intensification may follow (e.g., Morrison, 1996). Spatial diversity in productive forms is also increasingly highlighted, in contrast to Boserup's dismissal of contemporaneous diversity as representing merely incomplete steps in a progressive development. Contributors to Widgren and Sutton (2004), for example, highlight the existence of 'islands of intensive agriculture' in East Africa, highly localized regions in which intensive forms of production have been adopted even in the absence of cities, markets, or other conventional drivers and which contrast with larger surrounding areas characterized by more extensive forms of agriculture. Finally, in accord with moves toward a more inclusive view of production, many studies now weigh

cultural meanings of food products alongside concerns of labor efficiency or energetics. This emphasis on meaning is significant in that is also tends to displace causal assumptions predicated on biological necessity.

Specialization

The origins and development of specialized production have always been major concerns in archaeology. If intensified food production is often seen as undergirding social complexity, then specialization has been regarded as its index. Students of specialization draw on Marxian traditions, which integrate concern for the means and social relations of production with anthropological attention to culture. This research tradition, however, draws equally from Adam Smith in its attention to the division of labor and focus on exchange, as well as its often embedded assumptions about the nature of economic behavior. In their concern for social and political implications of specialization, archaeologists have also drawn on Durkheimian notions of solidarity and integration.

The Concept of Specialization

Specialization may be defined as the channeling of resources, skills, and/or labor into restricted ends, a definition focusing on both the products and process of specialization. Other definitions stress the role of specialization in setting apart people, technologies, and production locales, both physically and socioeconomically. Most literature on specialization in archaeology focuses on craft production; such studies have been dominated by a concern for technological process, interest in the organization of production, and, more recently, an expanded interest in the social relations of production, including issues such as identity and meaning. Specialization implies exchange on some level and as such, is not intelligible outside larger political/economic contexts.

History of Approaches to Specialization

Most early studies of artifacts emphasized typology, using morphology and manufacturing technology to classify objects, creating the chronological and spatial systematics that still underlie disciplinary practice. Despite pioneering studies such those of V. Gordon Childe that stressed the social and political roles of craft specialists in early stratified societies, most observations on artifact variability were oriented toward defining the cultural/temporal units that were themselves the goals of research. With moves toward functionalism in the 1950s and 1960s, however, technologies of production commanded greater attention as areas of study in their own right; this focus on technology continues into recent materials science approaches.

With the 1960s and 1970s came concerted efforts to delineate the organization of production and especially the integration of specialized producers into larger political economies. Growing from this interest, much effort has been spent investigating the scale (household production, workshops, and factories) and tempo (full- vs part-time specialists) of specialized production and the material correlates of organizational forms. Also of concern are forms of control over production, strategies of labor and resource mobilization, and the disposition of manufactured goods. Several classifications have attempted to capture some of these contextual dimensions of production, distribution, and consumption (Costin, 1991; Costin and Hagstrum, 1995), even as others have pointed to the potential for significant organizational diversity and fluidity in production, making such schemes difficult to apply (e.g., Sinopoli, 2003). Studies of exchange have been particularly important, congruent with a focus on regional economies and with the development of new analytical methods for determining source areas of raw materials.

Specialization studies have been marked by a concern for the initial causes of specialization as well as its intensification, although here explanations often stress socially based demands and especially the development of prestige goods, perhaps because many artifacts are clearly not biologically necessary for survival. More recently, archaeologists have begun to stress processes of production, especially agent-oriented *chaîne opératoire* approaches, which focus on structured chains of culturally inflected decisions made by producers (Lemmonier, 1986) and on interrelations between technology and meaning. A new focus on producers, too, has followed from concern for more finely divided aspects of producer identity, including gender and ethnicity and from recognition that multiple organizational forms of production often coexist, even where the producers are the same.

Consequences of Specialization

From the time of Childe, archaeologists have explicitly linked specialized production with complex political forms and social inequality (Brumfiel and Earle, 1987). The very existence of elites is typically inferred, in part, from sumptuary objects identified by their elaboration, restriction, and sometimes exotic provenance. Curiously, specialization in craft production (sometimes cast as intensification) is generally viewed as promoting efficiency, while intensified agriculture is depicted as producing declining marginal returns. Recent work on the meaning of production, especially its ritual context, draws more fully from an anthropological tradition de-emphasizing efficiency.

Methodological Issues in Specialization Studies

Recognizing specialized production begins with the objects and by-products of manufacturing and their distribution. The definition of specialization allows for certain ambiguities, as issues of scale and context impinge. For example, the production of artifacts in one region and exchange to another may be considered regional specialization, although artifacts were manufactured by every household. Locations such as quarries are specialized places without necessary associations with producer specialization. Although the goal of archaeological research is usually to identify producer specialization, because archaeological data are fundamentally spatial, determining the organization of production is inevitably inferential. Much of the methodological development of specialization studies grew around this dilemma. Complex technological requirements or high levels of producer skill are sometimes assumed to index

specialist manufacture; another criterion advanced for identifying specialization and its scale is standardization, mass production being thought to promote standardization (for reasons of efficiency). The possible link between specialization and standardization, especially in ceramic production, has long been under active discussion (e.g., Rice, 1991; Roux, 2003). Although ethnographic and experimental research has been important in studies of specialization since the 1960s, more recently such work has expanded beyond technical guidance to address broader concerns such as the reasons for community-wide specialization (Stark, 1991), and issues of identity, gender, power, and place. Both ethnoarchaeology and experimental archaeology now have dedicated academic journals of their own.

The Future of Specialization Studies

The trends identified in intensification studies also hold for studies of specialization. Concerns for process are implicated in perspectives that draw specialized production into the larger field of the anthropology of technology; this concern is sometimes expressed in the language of 'crafting' and the ways in which crafting both draws from and creates social relationships (Costin and Wright, 1998). Recent developments in the archaeology of both intensification and specialization tend to stress process over cause and explore the consequences of productive organization for differently situated social actors rather than classify productive forms along an evolutionary continuum.

Intentionality and Rationality

David Braddon-Mitchell, University of Sydney, NSW, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article discusses the central features of mental systems: intentionality and rationality. It considers rationality as the characteristic excellence of intentional states, most especially beliefs and desires, and explores the differences and similarities between conceptions of rationality in these two cases, as well as in the case of actions which arise from beliefs and desires.

Intentionality and rationality are the two essential features which, perhaps, are characteristics of a mind. Intentionality is that directedness which allows thoughts to be about other things, even about the world. Because the mind is an intentional system it can represent how things are. Rationality is the characteristic excellence of intentional states, both those that are about how it is (beliefs) and those about how one wants it to be (desires). The present article discusses the nature of intentionality, the question of what the objects of thought actually are, what relationship if any it has with consciousness, and some modern naturalistic (broadly scientific) accounts of what makes something intentional. It then considers the characteristic excellences of the intentional states of belief, desire, and of the events they result in, actions. The article concludes with a brief discussion of whether we in fact are rational, and of how to justify the normative claim that we ought to be rational.

Intentionality

Intentionality is the term given to the mind's striking capacity to have states which are about features in the world. In addition to weighing 3 g, or being composed of ectoplasmic goo, or conforming to a certain neural networking diagram, a mental state might have the property of being *about* something: perhaps *panna cotta* flavored gelato. This property – this 'aboutness' – is an intentional one. It is sometimes thought of as a kind of directedness. The mind is directed on things; your fears are directed on their objects; your beliefs likewise.

The term itself is derived from a Medieval Latin translation of an Arabic technical term. The medieval discussion was about a rather different topic than the contemporary issues that are discussed under the rubric of intentionality – perhaps slightly closer to the contemporary debate about the nature of concepts (Sorabji, 1991) (q.v. Concepts).

The World or Intermediate Objects?

A straightforward and appealing account of intentionality is to claim that it consists in some kind of relation between a mental state and the object it represents. This claim is neutral between the view that the relation is inexplicable by the natural sciences, and reductive naturalistic programs that try to explain just what scientifically mandated properties this relation is constituted by.

There are difficulties: presumably it is possible to have beliefs about things that do not exist. In some cases this can be finessed away – my belief about the gelato in the fridge, should there turn out to be no gelato in the fridge, might be redescribed as a (false) belief about the fusion of all gelato, that part of it is instantiated in the fridge. But such finessing is pointless, because there are *types* of things that do not exist, as when I have beliefs about Bunyips. So if my (false) belief about the Bunyips does not gain its intentionality in virtue of a relation between a mental state and Bunyips, what does the relation hold between?

One solution is that it holds between a mental state and a special, intermediate, intentional object. The intentional object might be there even if the mental state does not succeed in directing itself onto the world. This requires that there are such intentional objects to do the representational work. Some philosophers, including Meinong and latterly Routley and Zalta (Zalta, 1988), hold variations on the doctrine that there are such entities, but they do not have full fledged existence: the nonexistent (sometimes called Meinongian) objects have some other kind of being which is enough to do the work.

Some proponents of the Meinongian view can allow that intentionality is always relational, but that in the case of existing objects the relation is between the mental state and the existing object, and in the case of the nonexistent objects it is between the mental state and the nonexistent object. This requires them to say (in the case of a fear of a Yeti) that the nonexistent Yeti is the very same object as the thing you would be fearing if there really were Yeti.

Perhaps in favor of indirect objects is that it seems that the contents of our beliefs, desires, and so on are more finely discriminated than the things in the world. This can be noticed in the so-called referentially opaque conditions (a kind of intensional context: (q.v. Intensionality)). If Bill desires a Rosa brand Gelato, and if it so happens that Rosa brand is the worst in Sydney, most do not think that it follows straightforwardly that Bill desires the worst gelato in Sydney, even though the gelato he desires is (unbeknownst to him) the worst in Sydney. However, if some indirect intentional object is taken to be the content, then there might be two distinct intentional objects, only one of which is the object of Bill's desire, but both of which are themselves directed. One of the disturbing things about this approach is that it does not seem to solve the problem. How do the special intentional

objects do the work of ensuring that the states that are in relations to them get to be about things in the world? If it is a relation to the object in the world, then there is a regress problem. If not and there is just a mysterious power, then the mysterious power may as well be possessed by the mental state directly.

There is also difficulty for naturalists in seeing how mental states can bear relations to mysterious indirect objects. Finally, a more basic complaint is that even where there are such indirect entities, it seems that our thoughts are surely at least sometimes directly about the things in the world: it is the gelato itself Bill desires, not some intermediate object.

Intentionality and Consciousness

Some have thought that intentionality is a special feature that marks off mental phenomena from nonmental phenomena: all and only mental systems display intentionality. Something like this was intended by Brentano in the slogan claiming that intentionality is the 'mark of the mental.' This is not meant to be a nomenclatural claim which merely says that, by definition, if a system is too complex enough to be intentional then it is complex enough to be mental. Instead, it seems to proceed by some connection between consciousness and intentionality. Thus, John Searle (Searle, 1983), for example, thinks, that a physical system which could do whatever reductionists claim is enough for representation (see the following section) could none the less lack genuine intentionality, because it would not be *about* the thing it covaried with. The reasoning is that either such systems might not have what it takes for consciousness, and thus lack intentionality, or else the reverse: that since they might lack genuine intentionality, they might lack consciousness.

Reductive Approaches to Intentionality

Most common among contemporary approaches to intentionality are reductive attempts to say what scientifically respectable property of our minds it is that accounts for the difference between intentionality and nonintentionality.

The first of these approaches is to deny that the phenomenon of intentionality exists. So-called eliminative materialists (q.v. Eliminative Materialism) (e.g., Churchland, 1981) agree that we can specify scientifically respectable properties which, if they were instantiated, would guarantee that there is intentionality. But they do not think such properties are instantiated, and thus think science will discover there is no intentionality. Since their arguments depend on stringent principles for the existence of intentional entities, there are two ways for noneliminativist reductionists to argue against them: by accepting the standards and making the empirical claim that there are things of this nature, or by rejecting the standards.

Amongst those who think there is in fact intentionality in the natural world, there are, very broadly, four basic approaches in the contemporary literature: informational semantics, teleobiological theories, broadly functionalist theories, and instrumentalist theories.

Informational semantics is the view that intentionality occurs in the case of the mind only when there is covariation in between mental states and things in the world. Caveats about complexity, interrelatedness or causal, and logical dependence are often added to upgrade this condition to sufficiency. Versions of these theories can be found famously in pieces by Fred Dretske (1983) and Jerry Fodor (1990) (q.v. Content, Informational Semantics).

Objections to the view are legion, the most troubling being variations of the so-called misrepresentation problem. The problem is that in situations where there is obvious error, the theory denies that there is error. For suppose that we are trying to have a mental state about cats. It covaries with cats (i.e., it appears exactly when the agent is in the presence of cats), but occasionally – say about 1% of the time – it misfires in the dark and the state appears in the mind when a large rat is seen in the darkness. For simplicity, suppose nothing else causes this cat symbol in the head. Intuitively, it seems we should say the symbol is about cats, and occasionally we deploy that symbol to say false things of cats – as when we think that there is a cat there, but unbeknownst to us it is in fact a rat which has misled us. Unfortunately, the theory notes that there is perfect covariation: between the mental symbol on the one hand, and cats *or* rats. Thus it says the symbol is about cats or rats. And so thus we have in every case a *true* belief about of cats or rats – that they are present. Various solutions to this problem can be found in the works cited immediately above, but none uncontroversially works.

Another objection is that no purely correlational fact could account for the thought that intentional states do not just reliably indicate the state of the world, but rather such indication is what they are normatively *for*. Teleo-semantics purports to find a solution to this problem. This is the cluster of views around the work of Ruth Millikin (1984) and Karen Neander (1991), according to which evolutionary biology plays a central role. The leading idea is that states are genuinely representational because something like covariation is the *proper biological function* of the states (or is produced by states whose function is producing states of this sort). This in turn is cashed out evolutionarily: a state's proper biological function is whatever it did that caused it to be selected by natural selection. Thus a heart's function is to pump blood but not to make a noise, because while hearts have always made noises, these noises did not contribute to the fitness of those organisms with hearts, whereas pumping blood did. So, in the case of mental states, while there may be many mental states which correlate with external features of the world, only those that do so because it was advantageous during evolutionary history get to count as intentional states. Objections are of two kinds. The first kind is that the states discriminated in such ways may not turn out to be about even remotely the sorts of things that we imagine our intentional states pick out. The second kind involves worries about the historical individuation of mental states. If Creationism is true, for example, states would not be intentional – because they would have no evolutionary history. Alternately, if Creationism is true then intentionality is an entirely different thing from what it would be on the assumption that Creationism is false. This would raise questions about what is in

common between what is called 'intentionality' on the Creationist assumption, and what is called 'intentionality' on the standard assumption, that would make it right to give them the same name.

Functionalist theories say that intentionality is a phenomenon which arises when systems are complicated enough to interact with the environment in a complicated way. So what matters is not just how the things in the world affect the presence or absence of the state, but how the state interacts with other states to affect the world. A state gets to be a belief that ice-cream is around, and thus a belief, and thus intentional, not only because it is an indicator of ice-cream, but also because it potentially interacts with the world. Combined with desires for ice-cream it may cause ice-cream directed behavior. In most functionalist accounts, there are few constraints on what the internal nature of a mind has to be like to count as intentional, so long as that nature will cause the right interaction with the world (see Armstrong, 1968; Braddon-Mitchell and Jackson, 1996; Lewis, 1972).

The final major category is instrumentalism (q.v. Instrumentalism). An instrumentalist about intentionality sometimes thinks that there is no intentionality as such, but it is pragmatically useful to imagine there is, because it allows us to engage in intentional explanations of behavior, which are both quicker and more practical than the full neurophysical story. Strictly speaking, such views are versions of eliminativism which do not seek to eliminate *talk* of the properties they hold not to exist. Other theorists who are sometimes called instrumentalists hold that there are indeed intentional states, but that all it takes for a system to have intentional states is to produce effects in the world best predicted or explained by intentional talk (see e.g., Dennett, 1991) On some construals this kind of instrumentalism is close to functionalism, since like the functionalist the view is realist about intentional states, and like the functionalist it places few constraints on the intrinsic nature of the states insofar as that nature is not relevant to their causal or explanatory profile. The differences center around whether talk of states apt for prediction and explanation is a distinct way of typing the states from the functionalist's way of typing causally. The answers to these questions about the differences between functionalism and realist instrumentalism will depend in part on views about the relationships between causation and explanation.

Rationality

Introduction

If anything is common to various accounts of rationality, it is that rationality is a special excellence of the mind. Perhaps, it is to have one's higher mental processes functioning well. It must be narrowed down by excluding certain kinds of functioning – well functioning just in terms of crude computational power can be excluded. More controversially moral well functioning is often excluded (q.v. Ethical Rationalism).

It can be best thought of in terms of criticism: one can criticize various mental process as irrational. Many think that one can criticize as irrational someone who fails to draw obvious deductive inferences, one can criticize someone as irrational who has strange and bizarre patterns of change in desire (though this is controversial as we shall see later), and one can criticize as irrational someone who fails to act so as to bring about what he/she desires in the light of his/her beliefs. On the other hand it is more controversial whether one can criticize as irrational behavior or thought on the grounds that is immoral and virtually no one thinks that not being able to perform Herculean tasks of mental arithmetic is enough to count as irrationality.

This article will cover three domains: belief, desire, and practical reason, and the question of how much there is in common between what is called 'rationality' in these domains. There is also a question as to whether rationality is a feature of emotions: is it rationally required or prohibited to be in various emotional states in various circumstances (q.v. Emotions).

Rationality with respect to these domains has characteristic goals. The rational believer aims at truth, the rational desirer aims at best desires (perhaps here is a connexion with morality), and the rational actor aims to act in a way so as to satisfy his/her desire in the light of his/her beliefs. An unresolved issue is whether rationality is characterized as whatever processes bring about these goals (q.v. Externalism, Epistemology), or whether rationality can be characterized by the nature of the processes themselves, and we are lucky enough to live in a world where these processes do in fact bring about the goals on average better than other processes (q.v. Internalism, Epistemology).

Rationality of Belief

In the domain of beliefs, agents are held to be irrational if they form or revise beliefs in the wrong way. At least three kinds of belief-forming mechanisms are at issue: the source of initial beliefs, the updating of beliefs on the basis of evidence, and the deduction of the implications of these beliefs in the absence of further evidence.

There is no clear consensus on how initial beliefs should be sourced. Bayesian probability theory holds that there is no way of assessing the rightness of the initial probabilities that agents give to various claims about the world. Instead, the method for revising beliefs in the light of evidence is something that the theory specifies. So on this tradition, an agent's beliefs are rational just if they are revised in the light of evidence the way the theory specifies (see, e.g., Jeffrey, 1983, or for an accessible introduction to methods Lee, 2004 (q.v. Bayesianism)). There are competing systems for updating beliefs in the light of evidence (q.v. Inductive Logic, Belief Revision).

Some philosophers, however, grant special epistemological status to some initial beliefs (or probability assignments) depending on where they come from. Initial beliefs might be held to be held rationally insofar as they come from approved sources. These include the testimony of others (q.v. Testimony) or claims about sense impressions (q.v. Logical Positivism, Sense Data, Perception).

The rational constraints on drawing of inferences from existing beliefs unaided by further evidence are the domains of the various branches of deductive logic (q.v. Deductive Logic).

Of course, there is a richer sense of rationality in this area: the capacity to draw the *important* conclusions and ignore the irrelevant ones. Artificial intelligence researchers have long seen how irrational seeming a system will be that just sits and cranks out all the irrelevant consequences of what it believes (q.v. Frame Problem, Artificial Intelligence).

Rationality of Desire

Whilst most philosophers would allow that beliefs, or at least the process of change of belief, can be legitimately subject to criticism on grounds of rationality, there is less consensus in the case of desires. Hume's famous dictum that for all reason cares, he could prefer the scratching of his little finger to the destruction of an illustration of his idea that foundational desires are not subject to constraints of reason. An agent simply has the basic desires he/she has; the job of reason is to modify beliefs with the goal of truth, which in turn serves in the task of satisfying desires. A way of understanding the motivation for this is through considering the *point* of reason. If you think that reason has goals such as truth or the satisfaction of desire, then it is easy to see how belief formation can be irrational – it fails to track the truth – and how action can be irrational – it fails to satisfy desire in the light of belief. It is harder to see what goals basic desires have – though perhaps ease of satisfaction might accord with one of these desiderata, in which case a kind of quasi-Buddhist constraint might recommend itself, of desire minimization. It is here also that connexions between rationality and ethics might be drawn, since one constraint might be that the goal of desire is to motivate oneself toward the good life, and rational desires are those which do this (q.v. Rationalism, Ethics).

But even if there is no constraint on basic desires taken singly, there might be some constraints on combinations. In the same way that one can rationally criticize someone for inconsistent beliefs, on the grounds that not all can be true, one might criticize someone for incoherent desires, on the grounds that not all can be satisfied. But this will be a much messier business, for it is much less clear that there is anything wrong with a desire set not all of which can be satisfied. For contingently it is never the case that all our desires are satisfied, and it is hard to see why it is worse if this is elevated to a logical truth in the case where they cannot all be satisfied because two desires are logically exclusive. Indeed one can imagine that there might be some inconsistent desire sets which lead to greater flourishing than some consistent desire sets – in which case this constraint is at odds with the ethical one above. But supposing that it is a desideratum to have consistent desires, is 'rational' the right word to describe such sets? This might be thought to be an essentially terminological issue. Certainly the situation is isomorphic with the case of consistent beliefs, but whether the differences are small enough to justify using the same term may be an unsettleable piece of semantics.

There is a further question about desire evolution. How should desires change over time? Most grant that along with changes in beliefs, there are rationally mandated changes in instrumental desires. If I desire to be cured of disease, and I learn that a certain berry contains the cure, then I have a reason to acquire a desire to eat the berries in the service of my desire to be. But what of desire change over time under the impact of experience which is not grounded instrumentally? Some think that greater general consistency across time and other coherence factors are rational constraints. On this view, someone whose desires change all the time in apparently senseless ways, wishing for world peace and bananas 1 day, and world war and fruitlessness the next, is irrational. Certainly such a person in practice would have inconsistent desires (most desire happiness, and fluctuating desires is a sure-fire killer of that state). In these cases the view that costatisfiability is a requirement would be enough to claim that such a person is irrational. But even this seems like a questionable rational constraint. Inconsistent beliefs cannot both be true, so we know at least one of these beliefs is not true, and so at least one does not achieve the telos of belief. Certainly, the state of having desires which cannot be cosatisfied means that you cannot achieve the goal of having all your desires satisfied. But even that is not obviously a requirement of rationality. One might think that we ought to desire things which are, sadly, not cosatisfiable, if each of these is a proper object of desire. Perhaps we should desire both happiness and achievement. Perhaps it turns out that you cannot maximize both. Unfortunate; but not obvious evidence that you are irrational. And even if it is an irrational state, it does not follow (as it does in the belief case) that one these desires must itself not achieve the telos of desire. Only that having both does not. But what if the wildly fluctuating desires were always synchronically consistent? This would still be a very bad way to be, though the current writer thinks that it may be a borderline terminological matter whether there is enough in common between this malady and others to call it irrational rather than unfortunate.

What the question really boils down to is whether there is a theory of rational desire revision which is an analogue of the principle of rational belief revision (see Smith, 1994; Bradley, 2007).

Such a theory would require that a range of principles is used as principles of revision, such as the coherence principles discussed above. The problem, as we have seen, is in justifying any list of principles of desire revision that seem intuitively rational and showing that they are rational. In the case of principles of belief revision the justificatory role is played in showing that the principles are likely to lead to true beliefs. It is very hard to see what the analogue would be in the case of desires, barring satisfaction as the end of desire revision (sympathetic though this would be a quasi-Buddhist account of desire revision: remove the desires, so that there are very few left, and can all be easily satisfied).

One interesting approach is found in Smith (1994) and the following literature. Here the idea is that the rational principles of desire revision are the ones which lead to desiring the good, and it is success in this goal which justifies the intuitive list. The account also has the good as that which would be desired ideally, meaning that which we all would desire when revising our desires by the rational method of desire revision. The challenge for this account is persuading us that this is a nonviscous circularity, since the rational principles are understood as ones which lead to states which are themselves defined as states which are generated via the rational principles.

Rationality of Action

Rationality of action is most commonly called practical rationality. It is the kind of rationality which concerns the relations between one's beliefs and desires on the one hand, and one's actions on the other. If you desire ice-cream, if the ice-cream is in front of you, and if there are no conflicting desires or other impediments to eating it, then it is a principle of practical rationality that you should pick it up and lick. The noneater is practically irrational.

Sometimes practical rationality is characterized as reasoning *about* action. Some interpreters of Aristotle and Kant see their work in this way. Similarly, contemporary work on decision theory and game theory is often understood as what conclusions about what one *ought* to do should be drawn from premises about beliefs and desires. Another way of understanding practical rationality is the relationship between action itself and belief and desire. The difference is just that on the first way of understanding it one is practically irrational if one holds wrong *opinions* about how one should act given one's beliefs and desires, and thus it is special case of rationality about belief or theoretical reason. On the other way of understanding it, one is practically irrational if one actually acts in the wrong way given a set of beliefs and desires.

Much modern work on practical reason has focused on various calculi which either describe or prescribe how to act given one's beliefs and desires. Decision theory (see, e.g., Skyrms, 1986) (q.v. Decision Theory) is a family of theories which, on the assumption that features of the world relevant to one's decisions are themselves unaffected by those decisions, aims to give a precise account of how to choose. Game theory (q.v. Game Theory) is the calculus which has been developed to compare actions in situations where the situation itself depends on one's actions, as in many games, where one's own moves may determine the moves of others, and thus affect one's assumptions about how the world is that are relevant to choice (see, e.g., Elster, 1979).

One central philosophical worry with these theories stems from an account of what desires are. Decision and Game theory both aim, it seems, to prescribe how we should act. Thus, we ought to be able to rationally criticize someone who has acted irrationally and flouted the favored theory. Yet the most popular account of desires (or preferences as they are usually called in this literature) is the so-called revealed preference theory (q.v. Desires, Revealed Preference Theory of). According to revealed preference theory, one's desires are ascribed according to one's actions. In other words, you see what someone does, you make some assumptions about what they believe on the assumption that they are rational with respect to belief formation, and then assume that their desires are whatever it would take to produce the action. But then you can never criticize anyone's actions, for you can always attribute desires, however strange, that make sense of actions. According to revealed preference theory these are the desires that the person had.

In its most extreme version it is hard to use the theory to make recommendations about action as well. For it is hard to say what one's desires are until they are revealed in action and on strong versions they are *constituted* by the actions (among other things) so there is no fact of the matter.

So if the theories are to have prescriptive content, then we need a substantive theory of desire internal to the workings of the mind: a theory that is not tied so closely to what one actually does.

One phenomenon about which there has been a lot of philosophical discussion ever since Aristotle, and which is connected to these issues, is the so-called weakness of the will. Sometimes it seems that we act against our own desires. You might overwhelmingly desire to loose weight, resolve to avoid ice-cream, but eat it nonetheless. It might seem impossible to act against your desires if desire is constituted by actions, for there is a desire posited to explain any action. Theories of weakness of will divide between those that accept this, and posit sudden changes of desire or hidden desires to explain the behavior, and those that posit a nondesire-based mechanism that makes one sometimes behave against the all things considered desires one has at the time of the weak-willed act (q.v. Weakness of Will).

Much recent discussion of the rationality of action in decision theory is concerned with the conflict in special cases between two principles, dominance and maximizing expected utility, which intuitively seem both correct and unlikely to give clashing results (where by clashing results include cases where one principle makes no recommendations). Dominance reasoning is reasoning that proceeds by dividing the case into exhaustive possible scenarios, and showing that on each a certain action performs better, in contrast to expected utility calculations which multiply the utility of the action in each scenario by the probability of that scenario and sum these. There have for a long time been cases (q.v. Newcombe Problem) where these seem to come apart, but in cases where the implausibility of the setup has perhaps caused them to be unfairly neglected. More recently there have been shown to be well-defined games where expected utility gives no recommendation, but dominance does (see, e.g., Colyvan, 2006).

Are We Rational?

Recently, there has been much focus on the question of whether, as a matter of fact, we are rational or not. Much of this has focused on theoretical reason, or rationality about belief. Tests show that when examples of simple reasoning are given to even quite intelligent people, large proportions draw wrong inferences. Even simple modus ponens can be got wrong. Elementary statistical reason goes badly wrong, though how badly wrong it goes depends on how the information that subjects are expected to use to draw their conclusions is presented (see, e.g., Stich, 1990: Chapter 1).

There has sometimes seemed to be a debate about whether this view that irrationality is omnipresent conflicts with the views of some evolutionary psychologists who see the brain as a marvelously well engineered machine with many modules for making calculations about the environments in which it evolved. But there is surely no conflict. For what is marvelously engineered for the environments we evolved in need not be so great for our current one, and modules that calculate quickly and efficiently in demanding real-time environments are unlikely to use the same algorithms as would be best for giving considered opinions when time is not an issue (see Stich and Samuels, 2000; Kahneman et al., 1998).

Ought We be Rational?

What the question of whether we are rational or not does raise, though, is the issue of whether we ought to be. For if humans are in fact to a substantial extent not theoretically rational, then the claims that a theory of rationality has to be purely descriptive cannot be upheld. For it would be a false description. So perhaps this should be thought of as a purely normative, a theory of how we ought to think and act. And the question is why? If we lack of a foundational story about why one ought to adhere to some norms of thought, then either a skepticism about rationality or a relativism about rationality – the view that there are many sets of norms competing in the same domains, and there is no fact of the matter about which generally ought to be adopted – become attractive. The latter view has acquired some prominence in recent years (q.v. Relativism).

A leading problem for foundational accounts of the sources of the requirement to be rational is a set of considerations that arise from Carroll's Paradox (q.v. Carroll's Paradox) (Carroll, 1895). In its original form it's formulated with respect to modus ponens, the principle of belief revision which says that if you believe P and you believe $P \supset Q$, you should believe Q. Let us write the thing I might believe if I believe modus ponens as $P, P \supset Q \vdash Q$.

So now suppose I believe the following:

$$P,$$
$$P \supset Q$$
$$P, P \supset Q \vdash Q$$

I believe both P and that P implies Q, and I believe the principle that from P and $P \supset Q$, Q can be inferred.

Why should I conclude Q? It seems I could just believe all these things and not use my belief in modus ponens to infer Q. Well, the thought runs, perhaps there is another principle I need to believe. This is the principle that if you believe P, and you believe $P \supset Q$, and you believe modus ponens, you should infer Q. Let us write this as $P, P \supset Q, (P, P \supset Q \vdash Q) \vdash Q$.

But now it seems I could add that to my belief set and still not be obliged to use it to infer Q. The thought that we might add yet another principle – $P, P \supset Q, (P, P \supset Q \vdash Q), (P, P \supset Q, (P, P \supset Q \vdash Q) \vdash Q) \vdash Q$ – to our belief set leads us quickly to see that we are in the grip of a regress.

An obvious response is that I might infer Q (or perform some action in virtue of some principle of practical reason in the analogue of Carrol's Paradox for practical or normative reasons) just because I am disposed to reason with modus ponens. It's not a matter of more beliefs, it is about our dispositions. But then the paradox can be used to undermine the attempt to justify those dispositions. Perhaps I do reason with modus ponens. But why am I justified in so doing? Perhaps because I believe that I am justified in reasoning using it just if I believe it (or if it true, depending on the kind of justification in question). But what justifies that? Perhaps … and the regress reemerges.

One answer to the question of why we should adopt a set of rational norms is found in the pragmatic school: it will be somehow good for use or useful. But this is perilously subject to empirical refutation. For the evolutionary theories seem to suggest that aiming to achieve true beliefs at any cost is in fact not good for us. Perhaps quick and dirty solutions are more life preserving, even at the cost of falsehood. There is also speculation that optimism is a condition in which people systematically overestimate the likelihood of good outcomes and underestimate the likelihood of bad ones, whilst at the same time getting on better in life than the more accurate pessimists.

A more modest claim, but still unsatisfactory to many, is to make rationality itself a hypothetical imperative. Insofar as you care about truth, exhibit a theoretical reason. Insofar as you care about coherent desires, make them coherent. Insofar as you care about satisfying your desires, act so as to make them most likely to be satisfied in the light of your beliefs. Of course even the modest claim, to have any force, requires a principle very like practical reason: insofar as you care about something, follow the rule that will give it to you.

Rationality and Reasoning

The fact that rationality is often thought of as a characteristic human excellence, and so is the power of conscious thought, has sometimes led to a confusion between rationality and conscious, deliberate reasoning. In fact it is very useful to distinguish between them. Much of what we do is not the result of conscious deliberate reasoning (sometimes called ratiocination). We make decisions, pursue our goals, and act in a way which can be praised as rational or criticized as irrational, despite the fact that it may not happen in a conscious way. If it were only conscious deliberate reason that was rational, then rationality would be even harder to find than it is. Of course, in showing that a piece of cognition is rational, it sometimes helps to provide an argument which shows how the process can be *rationalized*: that is, described in a way that might look like a valid piece of deliberation or ratiocination. But this is not to say that this is what originally went on. Thus we might say of animals, even if we do not think they possess the power of conscious reasoning, that their mental processes are rational insofar as they process the information they receive about the world and respond in a rational way.

Abstract

The usual distinction between philosophical intentionality and psychological concrete intentions is here disregarded. That allows for a broader approach for studying the development of intentionality. Cognitive science, relying heavily on the concept of representation (e.g., goal representations), is compared to dynamic systems approach, which does not need to assume representations. As an alternative to a description of the development of concrete intentions in terms of goal directedness, that is, in terms of representations, dynamic systems approach opens for a perspective on the development of intentionality that provides better insight to the complexity and adaptability of human intentional behavior.

Introduction

In the late nineteenth century, the philosopher Franz Brentano (*see* Phenomenology: Philosophical Aspects), facing the emergence of psychology as a 'science of the mind,' wanted to distinguish between what was physical and what was mental about the human being. He considered mental phenomena – in contrast to physical phenomena – to have a directedness to something else than itself, and took the medieval scholastic term 'intentionality' to designate this characteristic of the mental. It may be manifest as our thinking being thinking of something. It means that the thought and what the thought is about is not the same thing. The thought is one thing, and the object of the thought is what the thought is directed toward.

However, if we go back to medieval prescholastic philosophy, we will find that Augustine was the first to use the word 'intentio' (in Latin). He was inspired by early Greek philosophy, where this directedness relationship also applies to perception and its object, to action and its object, as well as to will or desire and their object (what I want or desire) (Caston, 2008).

The Psychological Concept of Intention

Psychologists use to make a distinction between the philosophical concept of intentionality, as mental directedness, and the psychological concept of intention, meaning purpose. Many authors, however, while making the distinction, slip back into using 'intentionality' meaning 'purposefulness,' as opposed to concrete intentions linked to particular actions. This omission is actually in agreement with the above-mentioned roots of the concept in Greek philosophy. Intentions or intentional actions, as discussed by psychologists, also have their objects, for example, the glass that you grasp and the water you drink. Thus, such intentions could be subsumed under the same concept of intentionality that philosophers use. So did the philosopher Maurice Merleau-Ponty (1962), who joined the ancient Greeks by suggesting that also behavior may be intentionally directed, namely, toward what is around in the real world.

One reason for making the distinction between philosophical intentionality and psychological intentions could be to avoid ascribing mind to chimpanzees, while granting them purposes, for example, they may grasp an apple to eat it. That goes also for infants. However, in contemporary psychological literature on infant intentions, there is no mention of infant purposeful behavior. Instead of focusing on the action itself, it has been common to ask for its goal, that is, the end state to be achieved by the action (*see* Goal-Oriented Behavior among Human and Nonhuman Primates). Infant and toddler intentionality is discussed in terms of goal directedness.

This makes it necessary to consider the relationship between the concepts of intention, purpose, and goal. For example, one could argue that first you have an intention, then you act, with the purpose that corresponds to your intention, and finally you achieve the goal of your intention. This sounds like you having conceived an intention in your mind, then you have acted with your body, in order to make reality correspond to your goal, that is, you have changed reality to suit your mind. It would imply that purposeful action require mindful intentionality, in Brentano's sense. Such a conception would not grant chimps purposefulness.

What Is Intentional, and What Is Not?

If Brentano's idea is valid, then humans are intentional, and other species lack intentionality. However, if chimpanzees are not intentional and do better than small infants, we have to concede that infants come to the world as non-intentional beings. Eventually, they gain advantage over the chimps. So, they are in the unique position of becoming intentional. The development of infant intentionality is thus a privileged area of inquiry, where one needs to address the question what, actually, one should mean with the word. We will see that there are arguments for considering infants to be born as intentional beings, as well as for considering chimps, and even much simpler organisms to be intrinsically intentional.

Infant Intentionality in a Historical Perspective

William James

In the late nineteenth century, William James (*see* James, William (1842–1910)) characterized babies as a "blooming buzzing confusion" (1890: p. 488), where all sensory

impressions "fuse into a single undivided object for that mind." While using the concept of intention, in the sense of purpose and aim, he does not explain or discuss its emergence in infancy. We should notice, however, that he thinks pinpointing any particular intention will make it vanish from the ongoing stream of thought in which we, at any moment, are engaged (James, 1890: pp. 253ff). The particular intention, for example, to use a particular word in a spoken sentence, is a fugitive part of the whole that depends on the intention to convey the meaning of the sentence, which, in turn, depends on the context in which the sentence is spoken, and so on. In discussions on intentionality, this flow of consciousness, as James puts it – but we could as well say stream of thoughts, or of actions, or of behavior – is commonly overlooked, analyzing, by abstraction, this or that intention, this or that behavior. That works in the laboratory, with an appropriate experimental design. The challenge is to extract intentions from video observation of a fussy baby playing with toys, where intentions can be studied in a context.

James Mark Baldwin

Contemporary to William James, James Mark Baldwin (1892) was more outspoken on development, proposing a distinction between physiological, sensorimotor, and imitative processes. He saw the persistent, repeated imitation (*see* Imitation during Infancy and Early Childhood), to achieve perfection, as the first sign of conscious volition. What is conscious is primarily what is immediately given here and now as sensations. With persistent imitation, however, the infant shows proof of having in consciousness 'a copy' of an absent thing or event that it wants to imitate, not giving up until having obtained satisfaction with its own behavior relative to the target.

Jean Piaget

Jean Piaget (1962; *see* Piaget's Theory of Cognitive Development; Piaget, Jean (1896–1980)) also discussed imitation, however, not its role for the development of intentionality, but for the development of language and thinking. He emphasized the absence of the imitated model as the most important feature; for example, when his daughter Jacqueline imitates the temper tantrum of another child she had observed the day before, implying that she has what Baldwin would call a copy of the other child's behavior in her mind. For Piaget, such imitation, in the absence of the model, is the starting point for mentally representing absent things and events. While Baldwin does not account for but rather presupposes the mental copy in humans, for Piaget the displayed imitation may become a mental object by a process of internalization, thus laying the basis for developing a mental capacity that is particular to humans, eventually also including mental images and symbols. This allows us to 'manipulate' mental representations of objects in the mind rather than with our senses and muscles in the physical world. Eventually, some mental representations are also externalized, as drawings etc., as well as spoken or written language.

Such mental manipulation could well illustrate Brentano's conception of intentionality. That was not what Piaget meant, however, and the closest we come to the concept of intentionality is Piaget's description of the means–end relationships, that is, when the infant chooses the right means to obtain a desired end.

Lev Vygotsky

Lev Vygotsky (*see* Vygotsky's Theory of Cognitive Development), in the Soviet Union, was also preoccupied with the use of symbols and he used internalization to explain the emergence of thinking. However, instead of starting with internalization of imitations, he went directly to language, stressing its social function. Through language the child internalizes social relationships. Vygotsky thus gave thinking a social origin. From the perspective of intentionality, the influence of Vygotsky has been to give increased focus on intentional content, that is, the particular object of a thought, or the purpose of an action. By that, intentionality becomes less of a general and abstract function of human mind, and more of a world-related integration of relationships with the physical and social experiences in a person's life.

However, Vygotsky's own view on volition imposed strict requirements on children's actions for them to count as intentional. He required full consciousness (Vygotsky, 1987: p. 213), as, for example, when learning a foreign language through deliberate study of grammar and vocabulary, something quite different from the spontaneous learning of a mother tongue.

Jerome Bruner

Jerome Bruner (*see* Bruner's Theory of Cognitive Development), who helped introduce Vygotsky to Western academic psychology, was explicit on intentions: "An intention is present when an individual operates persistently toward achieving an end state, chooses among alternative means and/or routes to achieve that end state, persists in deploying means and corrects the deployment of means to get closer to the end state, and finally ceases the line of activity when specifiable features of the state are achieved. The elements of the cycle, then, comprise aim, option of means, persistence and correction, and a terminal stop order" (Bruner, 1981: p. 41). This covers both the persistence and the means–end relationship. While there is no principled difference between Piaget and Bruner on the nature of intentionality, Bruner was inspired by Vygotsky to pay more attention to the role of the child's social environment in the development of infant intentionality.

Cognitive Science

In the 1960s and 1970s, modern infant research revealed extensive skills and potentials of the human infant already at birth, something that may be contrasted with James' famous dictum mentioned here above, as well as with Piaget's view of infancy. These skills supported reactions against behaviorism concerning language and cognitive development and revived the idea of innateness, widely accepted since Chomsky's critique of Skinnerian behaviorism in the beginning 1960s. 'The cognitive revolution' that followed gave birth to a new paradigm in

psychology, cognitive science (CS), with tight interdisciplinary links to, for example, linguistics and neuroscience (Thagard, 2012). It had great impact on infant research, including on the development of intentionality.

The CS terminology and its view on the relationship between organism (person) and its environment are based on 'the computer metaphor.' This implies that information from the environment is experienced, understood, reacted to, and acted upon only after being processed by the mind, or by the brain. CS thus outlines an 'information processing' translation between the organism and the world. Information received through the senses needs to be matched with some representational content of the mental or neurophysiological apparatus that is adequate for the situation and, vice versa, from there to the body for adequate action to be executed. Eventually, CS has come far in recognizing the interactional character of such processes, but the paradigm remains the same; representations are considered as a necessary intermediary, and at the same time a dividing line between the organism and the world.

The Cognitive Science Concept of Representation

This concept of representation is thus different from Piaget's use of the same word. (There are, however, affinities between Piaget's theory and CS; the concept of 'schema' (*see* Piaget's Theory of Cognitive Development) in Piaget's theory resembles the CS concept of representation.) It first referred to something more 'mental' or abstract, such as denoted by Jerry Fodor's (1975) expression 'language of thought,' based on rule-governed relationships similar to the structure of natural languages. It then changed to be specified as 'motor' or 'neurological' representations, denoting neuromuscular or brain structures that underpin and correspond to particular behaviors, feelings, thoughts, etc. (*see* Concept Learning and Representation: Models; Knowledge Representation; Logics for Knowledge Representation; Cognitive Neuroscience; Neural Representations of Objects; Reference and Representation: Philosophical Aspects).

This is true also for the understanding of infant intentionality; Bruner (1981) stands for the earlier view, depicting intentionality in terms of action toward end states. Vittorio Gallese (2010) illustrates well the latter use of representations for the study of intentionality. He proposes a particular "intentional type of representation: a representation specifically and exclusively coded under a distinct type of motor neural activity pattern, one involving dynamic organism–object relations" (p. 205). What is represented is thus a particular type of interaction between an agent and the world he/she is acting upon. Furthermore, Gallese (p. 207) is explicit on the representational character of goals. Goals do not exist in the world other than as representations of goal states. To conclude, one may say that the development of infant intentionality from a CS perspective amounts to the development of goal representations and representations of actions to achieve goals.

Infant Intentionality as Goal Directedness

While Bruner understands goals and goal-directed action as mentally represented and Gallese has a neurophysiological understanding of the same concepts, Michael Lewis (1990) proposed a wider understanding of goal directedness. He noticed that infants, from 2 months of age, having gained control over a pleasant stimulus through its own action, did not stop trying when the triggering action failed to bring forth the stimulus, as would be predicted by a simple associative learning paradigm. Instead, the child was frustrated and increased its efforts to make the stimulus reappear. Lewis explains the results from a principled standpoint, that "all goal-directed systems are intentional" (Lewis, 1990, passim); thus these experimental results are a demonstration of infant intentionality already at 2 months and not just 'circulary reactions,' as Piaget had claimed (*see* Piaget's Theory of Cognitive Development).

Lewis relates goals to emotions, as desires. Ultimately, they serve the survival of the individual and thus have an evolutionary background. It would simply mean that survival depends on behavior having the purpose to seek pleasant emotions and to avoid unpleasant ones. Goal-directedness thus becomes the basic condition for life at any organismic level, and so would include "the intrinsic goal-directedness in the behavior of living eukaryotic cells," as proposed by Tecumseh Ficht (2008: p. 157). It would then resemble Humberto Maturana and Francisco Varela's (1980) concept of 'autopoiesis' (*see* Law, Autopoiesis in), which literally means 'self-creation,' referring to the capability of cells and organisms to maintain themselves, and, if necessary, repair themselves and change themselves through an active use of resources from the environment.

From there, Lewis conceives a developmental trajectory for intentionality, where emotion is successively complemented by cognition and, at the end, by metacognition (conscious awareness of own cognition, Lewis, 1990: p. 244, not verbatim). Five different levels of intentionality are then to be considered as levels of the self-regulation of the individual organism, from "a plant's movement toward the sun, a newborn child's movement toward a brightly colored object, and an adult's conscious goal-directed behavior" (Lewis, 1990: p. 231). Thus, we have a very broad span of different conceptions of goal-directedness, from autopoiesis, over means–ends relationships (Piaget and Bruner), to explicit conscious planning, as we saw with Vygotsky. They are all covered by Lewis' proposal on levels of intentionality. Only the highest level would satisfy Brentano's conception of intentionality.

Social Intentionality

One particularly advantageous asset of the human species is that we are social about our intentions, to an extent not found in any other species. Therefore, an interesting question is how do infants become social about own and other humans' intentions.

Theory of Mind

David Premack and Guy Woodruff (1978) introduced the concept 'theory of mind' (*see* Theory of Mind during Infancy and Early Childhood and Cultural Variation, Development of;

Mind, Theories of; Intentionality in Language and Communications), asking whether chimpanzees take into account that other beings, as well as themselves, have mental states, that is, beliefs, desires, opinions, and even pretense ('false beliefs'). This proposal gained huge success, engendering a host of research aimed at exploring what kind of theory of mind infants and possibly primates might have at different ages.

Eventually, two different conceptions of theory of mind emerged. On the one hand, 'theory' should be taken literally, that is, a kid would have a particular ('folk psychology') notion that there is something called 'mind' and that this mind to a substantial degree influences what people do and say. This interpretation was named "*theory* theory of mind." On the other hand, a bundle of what were labeled 'simulation theories' came to the fore. Research showing a parallel development in the understanding of own actions' goal-directedness and of the goal-directedness of other persons' actions supported proposals that infants associate own action to other people's actions (e.g., Sommerville and Woodward, 2010).

Mirror Neurons

Simulation theories also gained support from the discovery of 'mirror neurons' (*see* Mirror Neurons, Theory of), which fired both when a subject carried out an action and when it perceived someone else carrying out the same action (e.g., Gallese, 2010). An important point is that the activation of these neurons is not linked to the particular motor movement patterns used by the actor, but to what is considered as the goal of the action, that is, its anticipated outcome.

Thus, there has been an increased interest in the importance of social interaction for cognitive development, including the development of intentionality, spanning from sociocultural (Vygotsky) to neurophysiological approaches. We now turn to one of the strongest manifestation of this interest.

Infant Intersubjectivity

The research on infant intentionality within the CS paradigm has been conducted almost exclusively in laboratories. The point of laboratories is experimental control, such that you can be sure about the relationships between experimental variables, for example, whether awareness of own intentions goes hand in hand with awareness of other people's intentions.

Innate Intentionality

Colwyn Trevarthen had a different methodological approach. He studied the development of infant intentionality through longitudinal live video recordings of natural mother–infant interaction. He proposed that intentionality was innate, most strongly stated in a book chapter written together with Penelope Hubley: "We conceptualize this development to be by differentiation of a fundamentally coherent field of intentionality which is, however, already anatomically partitioned at birth into three modes out of which three kinds of experience and action are generated postnatally. These modes are probably three real systems of the brain that achieve functional differentiation by interaction with each other and with the environment." The three modes he conceived were "Forms of action and perceptual processing appropriate for (1) knowing and using objects (praxic mode), for (2) communicating with the human world (communicative mode), and for (3) acting in self-directed or thoughtful manner (reflective mode) appear as distinct rudiments in the newborn" (Trevarthen and Hubley, 1978: p. 213).

Other researchers have substantiated Trevarthen's proposals on the two first modes by reporting a capability for imitation (*see* Neonatal Imitation) already at birth (Kugiumutzakis, 1999) and different movement styles toward persons and toward things (Rönnqvist and Hofsten, 1994). Trevarthen used these two first modes, the praxic and the communicative mode, as elements in a three-stage model for the development of infant intentionality, where, in the first stage, the child between 2 and 4 months shows an advanced social intentionality in interaction with a parent, in what Trevarthen labeled 'primary intersubjectivity' (communicative mode). Between 4 and 9 months, as the child gains better motor control, this social interaction gives way in large part to interaction with things (praxic mode). Finally, from 9 months, the child coordinates, in 'secondary intersubjectivity,' interaction with things within social interaction, such that the social interaction itself may be about things (communicative and praxic modes combined). The difference between primary and secondary intersubjectivity is thus that first the interaction is only about mother and infant, where, as it were, the dyad is shielded from the world outside. In secondary intersubjectivity, however, the dyad is able to include the outside world, in terms of, for example, a toy, such that child and adult may share experiences (*see* Joint Attention during Infancy and Early Childhood Across Cultures) of the toy. For the younger child, then, it is either social interaction or interaction with the toy, later it is both together.

Intentionality as Organism–World Relationship

This three-stage model was not followed up in Trevarthen's later writings, which might have something to do with this understanding of intentionality being incompatible with the above-mentioned definition of the concept proposed by Bruner. Inspired by Merleau-Ponty (mentioned in the Introduction section), Vedeler (e.g., 1991) suggested that the common understanding of intentions in terms of goals could be replaced by a more general concept, in particular, concerning infant intentionality, as 'behavioral object-directedness.' Merelau-Ponty (1962: p. 138) writes: "In the action of the hand which is raised towards an object is contained a reference to the object, not as an object represented, but as that highly specific thing towards which we project ourselves" (quoted in Vedeler, 1991: p. 439). That would imply shifting focus from a cognitive to a behavioral and relational understanding of intentionality, thus avoiding a discussion about whether infants possess the mental capacity of having intentions, and instead addressing what Trevarthen observed, namely, the skills infants develop in handling both people and things, and the coordination of the two.

While never properly defining 'intention' and 'intentionality,' it is very clear that Trevarthen uses these words to describe particular relations the baby has to its environment. When it comes to secondary intersubjectivity, the important

conclusion he draws is that the coordination of person-directed and thing-directed intentions is the starting point for the development of human thinking and language. I suggest that it is also the starting point for the development in humans, both of what most philosophers mean with intentionality and what psychologists meant with intentions.

The third, reflective, mode of intentionality is not elaborated to the same degree, although Trevarthen later proposed a third, tertiary level of intersubjectivity, where child and adult are able to share meanings about things, as well as about self and others. However, this level corresponds roughly to the child's having a theory of mind, as mentioned here above.

Trevarthen uses the word 'representation' sparsely, although he seems not to oppose the CS understanding of it. The quote from him here above about the three modes of intentionality as real systems in the brain cannot be understood as anything else than hypothetical neurological representations. Also, while it has not been possible to find any statement from himself on the subject, the mirror neurons findings have generally been considered as support for his proposals on innate intersubjectivity.

Dynamic Systems Approach

Many have argued that the CS conception of representations is not necessary – and is also misleading – for describing the organism–environment relationship (cf, e.g., Costall, 2007). Several nonrepresentational approaches have been proposed. Many of them try to find a common ground with CS. Not having the space to here present several criticisms and alternative views, I choose one view, namely, dynamic systems approach (DSA) (*see* Self-Organizing Dynamical Systems, probably only about mathematical application of DSA. Certainly indispensable for understanding, but not giving full justice to the scope of possible applications). I consider DSA to have the greatest potential to offer a consistent alternative to CS.

No Need for Representations

There have been many attempts to integrate DSA into CS. In my view, however, they have not been convincing. The stumbling block is the concept of representation. While CS relies heavily on this concept, in DSA it is not needed. Things in the world and neurophysiological structures in the body (as well as the body as such) are what they are. Thus, they are on par. This means that components of a dynamic system may be both organismic and environmental, and neither have precedence over the other. If you want to calculate the product of two three-digit numbers, you may do it mentally or you may use a calculator. With the calculator, you include a component from the environment in the system you assemble for the solution of the multiplication task.

Most importantly, mental or neurophysiological structures do not represent things and events in the world. For example, brain structures consist of systems of neurons related to each other by synaptic facilitation and inhibition. That's what they are, and nothing more. Inactive, they are just a heap of neurons. They are activated if they are relevant for the solution of a task. For example, they may work together for the solution of the multiplication task. However, if, for example, the neurons in question are not well enough integrated for the task (i.e., you are not good at math), other resources might be preferred, for example, a calculator. The involvement of the brain in the task will then be quite different (e.g., pushing the digit buttons on the calculator and reading the screen).

Representations and Change

The organism is under constant transformation, as long as it is alive; for example, the world and own activity induce experiences that change synaptic links in the brain. If structures of synaptic links are to be considered as representations, it would mean that they keep their structure roughly unchanged, being activated in different situations. Anatomically, however, changes do take place, and – in all living organisms – subsequent changes depend on previous changes, such that the history of the organism becomes important. This is particularly true for humans, who mentally accumulate and retrieve experiences to an extent not found in any other species. If structures of synaptic links were to be considered as representations, the 'sameness' of some particular neuroanatomical structure would be relative, and it would be a question, at each moment, whether it is relevant or not. If not, it would no longer work as a representation.

Resources Instead of Representations

The question whether such neural structures are innate or acquired would then be beside the point. From a DS perspective, it is preferable to consider such structures as resources. Consider representations as 'hardwired': they are innate, selected by evolution, refined, developed, and adapted by experiences. While being adaptable to different situations, their function should be basically the same from time to time. Resources, on the other hand, are temporary and contingent on the situation. Are they useful or not? That depends. Sometimes some particular neuroanatomical configuration for any individual organism could be recruited to solve a particular task in a particular situation.

By habits and routines, organisms tend to assemble the same resources for similar tasks in similar situations. Thus, they help generalizing and automatizing, such that daily life becomes easier, although it may also result in malfunctioning and mistakes. However, it is always an open question which resources will be recruited in any particular situation. In DSA language, it is called 'soft assembly' (e.g., Thelen and Smith, 1994: p. 60). There are no fixed rules, no grammar, no store of solutions for solving tasks. Each situation is unique. Even if you have a strong habit for mental calculation, whether you choose to use your head or the calculator to solve your multiplication task – even for the same constellation of digits – may depend on the situation: how well you slept last night, how sure you need to be about the product, the availability of the calculator, etc.

The Impact of Dynamic Systems Approach

DSA gains increasing influence in psychology. It is not a coherent paradigm to the same degree as CS and is very

differently interpreted and used by different researches (Lewis, 2000). Shaun Gallagher (2008), as a philosopher particularly interested in neurophysiology, argues for a DSA to the analysis and explanation of intentional action. He also features the social dimension in the development of intentional action and revives Trevarthen's concepts of primary and secondary intersubjectivity mentioned here above. Ester Thelen and her group have provided the most well-known and referred to application of DSA focused on infant motor development (e.g., Thelen and Smith, 1994). In my view, the caveat is that, while to a great extent taking an antirepresentational stance, most DSA research and publications implicating intentionality – Thelen's work included – describe infant intentional actions in terms of goals and goal-directedness.

Developing through Relationships

Alan Fogel (e.g., 1993) is an exception. Based on a DSA, both methodologically and theoretically, he uses longitudinal (*see* Longitudinal Data: Event–History Analysis in Discrete Time; Longitudinal Data: Event–History Analysis in Discrete Time; Longitudinal Research: Panel Retention) video observations of live mother–infant interaction (*see* Qualitative Methodology in Developmental Psychology; Qualitative Research), where the mother and the infant are considered as one single dynamic system, and also the unit of analysis. Instead of assuming child and mother to have individual, possibly concurrent, goals, Fogel suggests that ongoing interaction organizes itself into creative achievements, where the history of the dyad in similar settings plays a central role for the further deployment of the interaction. Instead of assuming intended goals for individual actions, Fogel's approach focuses on the ongoing interaction, based on habits and routines that give the present situation its historical context and emotional color, and within which new purposes may emerge.

As an example, Vedeler (Vedeler and Garvey, 2009) used Fogel's methodology in following the transition toward secondary intersubjectivity in Trevarthen's tripartition of the development of infant intentionality. The point of the investigation was to explore the contextual resources for the coordination of social intentions with thing-oriented intentions before full-blown secondary intersubjectivity, the word 'intention' being understood as object-directed action, whether social objects or things. Weekly recordings of a recurring setting, involving a fixed set of toys, revealed the emergence over time of shared experiences of toy properties as resources for the play (cf Costall, 2007: pp. 68ff, on affordances). These new resources are, in turn, selected for further play with the same toy. Thus, situated shared experiences promote the emergence of a new kind of intentions regarding the toy, which may then become routines, later recruited for further and different tasks in the future.

Perspectives for Future Research

As to the future for research on the development of infant intentionality, I see two possibilities. Within a short perspective, most research in the area will be guided by the CS approach. In a longer perspective, however, DSA will prevail.

The CS vision of human cognitive functioning is based on laboratory findings. In DSA, reality is also, to a large extent, simplified, as one tries to find the essential components that are recruited for a particular kind of task solutions. Mathematically oriented proponents of DSA (*see* Self-Organizing Dynamical Systems) are operating with as few variables as possible. However, reality is infinitely complex. A more relaxed, 'metaphorical' use of the DSA concepts is less specific on the variables, but gains in ecological validity. This will give more importance to context and social interaction.

In this perspective, Fogel's approach might be the best candidate for giving a theoretically consistent alternative to the CS approach in studying the development of infant and early childhood intentionality. It should then not be considered as the growth of any particular mental or neurophysiological function, but as a manifestation of an activity relationship with the world, common for all living organisms, most salient, however, in the species *Homo sapiens*, having a unique skill in drawing on social resources for solution of daily life tasks.

Trevarthen was the first to draw attention to the details of early infant social propensities. With the concept of secondary intersubjectivity, he also proposed a theoretical model for human intentionality as a starting point for the development of human cognition. From a CS perspective, Trevarthen's model gains support from neurological findings, in particular on mirror neurons. He also receives recognition, in passing, from several prominent CS scholars on infant intentionality, although they rarely draw upon his model. From a DSA perspective, however, it would be wrong to assume an innate intentionality to describe primary and secondary intersubjectivity. No doubt, there are both neurological and other anatomical features of the newborn human infant (in its brain, but also, for example, the complexity of facial and finger muscles) that may be excellent resources for social interaction and manipulative skills. From there, intentions may emerge as the intricate mutuality of social interaction between mother and infant gaining particular impetus from being combined with manipulative skills.

Whether from a CS or a DSA perspective, there is by now unanimity on the importance of social interaction for human cognitive development, and thus also for intentionality in Brentano's sense. We are all developing through relationships, as the title of Fogel's (1993) book tells.

Abstract

The attribution of intentionality is the ability to view another's actions, behaviors, gestures, or speech as having a purpose. The emergence of intentionality in infants is thought to be a foundational feature of human communication and language. We will first discuss those issues, then trace children's developmental pathway from preverbal cognitive skills such as eye contact, joint attention, intention reading and sharing to attribution of mental states (Theory of Mind), and their link to language use. We will finally focus on the role of the input and of adult scaffolding in the development of those social-cognitive abilities.

Introduction

Following Piaget (1962) and Vygotsky (1962), nonnativist scientists agree that language emerges from nonverbal cognitive and social development in infancy. The subsequent research has strived to investigate how early perceptual-cognitive capacities pave the way for language and communication. Even though children have innate biological and cognitive capacities, they need to learn conventions and formal patterns from communication and language in their environment. They gradually become fully bloomed interacting speakers building on such cognitive and social skills as the ability to follow another's gaze, to draw and maintain their attention, to imitate, to read others' intentions, to make analogies, to categorize, and to symbolize.

A wealth of studies have shown that it is the interaction and complementarity between basic perceptual, cognitive, affective processes and a favorable environment that involves caring adults or older siblings constantly adjusting their behavior to the infants' that seem to trigger and guide the emergence of shared attention and intentionality which will then lead the child into symbolic communication.

We will first present the notions of intentionality and Theory of Mind as possible foundational features for human communication and language; we will then describe the child's developmental pathway from preverbal cognitive skills to language use and finally focus on the role of the input and of adult scaffolding.

Intentionality and Theory of Mind

Definitions

The word 'intentionality' comes from the Latin 'intendere' which means to aim in a certain direction for a target. The attribution of intentionality is the ability to view another's actions, behaviors and production of gesture or speech as having a purpose. Toddlers can exhibit the understanding of intentions for example by handing over his car keys to their father who has just said 'good-bye' in the morning and is restlessly looking everywhere as he does almost every morning. The repetition of the same scenario enables the child to memorize the sequence of events and to provide the missing keys. Infants can also show that they have an intention when communicating the need to be given the ball, which is out of reach by looking and pointing at the ball as well as pulling the adult's sleeve.

According to Baron-Cohen (1991), the infant's understanding of intentions in others, a social skill found by 7–9 months of age, is a 'critical precursor' to the development of 'Theory of Mind' (ToM). ToM is the ability to attribute mental states, such as beliefs, intentions, memories, and desires to oneself and to others. It enables us to understand that mental states can be the cause of others' actions or behaviors. We only assume that others have minds based on analogy to ourselves and thanks to our participation in social interactions.

Theory of mind develops over time. It is constructed on the basis of precursor skills all the way to the understanding of mental states and their link to behaviors. Those precursor skills include joint attention (the ability to attend to or direct attention to a common object), intention reading, understanding that other people have different perspectives, use of cognitive and mental state verbal expressions, of pronoun reversals, and pretend play. Communication itself is triggered by the intention to share objects, properties, or states of affairs that are in our minds. Intentionality in communication corresponds to the encoding of messages *for* others.

A Foundational Feature of Human Communication and Language

Since the influential article by primatologists David Premack and Guy Woodruff entitled "Does the chimpanzee have a theory of mind?" (1978), much empirical research has been undertaken in investigating whether nonhuman primates can ascribe psychological states with intentionality to others and how human children develop this capacity. At the end of the twentieth century, human cognition and animal cognition were shown to differ in one important respect: our ability to understand intentions and to "take another's perspective." For Tomasello (1999), it is the very crucial biologically determined factor that distinguishes humans from primates and could also be deficient in autistic children. The emergence of intentionality is viewed as foundational because it provides the matrix to understand what others are doing.

According to Tomasello, at an important point in his/her cognitive development, between 9 and 12 months old, the child comes to experience himself/herself as an intentional agent – that is he/she views his/her behaviors as structured by goals. As he/she identifies with the adults around him/her, he/she automatically views them as intentional agents as well. Tomasello's theory, developed thanks to a wealth of

experimental studies, consists of a demonstration that all kinds of human cognitive abilities emerge from the exploitation of this basic human capacity and are transmitted culturally. Communication and language are part of those specifically human cognitive abilities that develop on the basis of this capacity. It is only because young children understand others as intentional agents that they can acquire and learn linguistic symbols: they begin to understand that their conversational partners are using these symbols to direct their actions and attention to outside entities. These symbols are organized according to conventional patterns and mutually shared rules and can only be transmitted through social learning.

Since 1999, a series of experiments has shown that though autism involves significant difficulties in understanding mental states that might be related to difficulties in processes as basic as on-line perception, which hamper their ability to respond to social stimuli such as vocal and facial expressions, autistic children and great apes understand intentions better than what was expected. They do not however engage socially with others in the way that typical children do. In more recent work, Tomasello et al. have attenuated their monolithic depiction of social cognition by giving a more gradual view (Tomasello and Rakoczy, 2003) and have suggested that an additional capacity was needed: shared intentionality (Tomasello et al., 2005). They suggest that only human beings can cooperate with each other and that it is that unique feature that allows humans to engage in the creation and use of linguistic symbols.

Children's awareness of other people's intentions, thoughts, and beliefs can only be inferred through what they do in experimental and naturalistic situations and there could be contradicting interpretations of their behaviors. Most of the evidence involving relationships between language development and theory of mind is built on correlations. It is probably premature to say that certain milestones are necessary for Theory of Mind development. But there might be an important impact of the lack of symbolic input on deficits in intentionality sharing and Theory of Mind. Indeed deaf children with no cochlear implant who do not have sign language as their first language perform very poorly as early as 18 months old in very basic tasks (Meristo et al., 2012) and at later ages perform similarly to autistic children in false belief tasks (Peterson and Siegal, 2000), whereas deaf signers perform to the same level as their hearing peers. Though the actual link between the tasks testing false beliefs and Theory of mind itself can be questioned, ToM seems to be highly dependent on specific interactive experiences during which adults behave and adjust to their infants' inferred mental states as well as they comment verbally about them. The major factor in explaining late-signing deaf children's delayed ToM development seems to be the reduced early experience of conversation and its role in perspective taking and mind sharing.

There seem to be complex interdependencies between language and Theory of Mind. It begins in infancy with joint attention and awareness of intentionality, and it continues with children's increasing use of mental state terms.

Mirror Neurons, Intentionality, and Theory of Mind

Researchers noted that certain neurons located in the prefrontal motor cortex of monkeys fired when the animals carried out an action and when they observed the same action carried out by another individual, suggesting that these neurons are important for encoding the intentions of others (Gallese et al., 1996). Since then, a number of researchers have underlined that the mirror-neuron system is an important component of the social-cognitive network. There is some evidence for impaired functioning of this system in autism. In order to understand the relationship between the processes involved in the mirror-neuron phenomena (such as imitation and empathy) and other aspects of communication and language, including theory of mind, it is now necessary to conduct longitudinal studies beginning before the onset of language and communication and of autism symptoms. Systematic neuroimaging studies should also be conducted to explore the deficits implicated in autism.

The Developmental Pathway

From Eye Contact to Shared Goals

Infants prefer their parents' faces and voices to other stimuli. They attend to their interaction partner and make eye contact almost from birth. They understand self-produced motion just a few months after birth (Bertenthal, 1996). They soon turn to look in the same direction as the adult. Woodward (1999) explains that around the age of 6 months, children make a difference between what can be expected from human beings who can reach for an object, and inanimate objects, who are not expected to reach for the same objects in similar circumstances. By 10 months, children can segment streams of continuous behavior into units (Baldwin et al., 2001). In studies involving obstacles, infants are shown to understand trying (Gergely et al., 1995). They also understand that when they succeed, adults will stop trying (Tomasello et al., 2005). Between 9 and 10 months, children engage in triadic situations involving themselves, an adult, and an object: activities such as giving and taking an object, throwing a ball to each other, putting toys away together, pointing-and-naming games. Children's gaze and actions demonstrate that they are coordinated with the other. The adult and child create a shared goal that they are going to reach together. However it is not until 12–15 months that children become involved in active joint engagement, sometimes taking the lead for they seem to understand the actual goal of the activity (Bakeman and Adamson, 1984). Not only are children able to share goals and coordinate their actions to the adults', they can also coordinate or reverse roles and take initiatives. It is around the same period that children try themselves to establish joint attention with others through pointing or other types of gestures.

Motor Control in Vocal and Gestural Productions

Children's ability to imitate adults in vocal and gestural productions shows that they make connections between their perceptions and their own actions and between their own bodies and the others'.

Before children produce their first words, they are able to systematically use prosodic cues to express a set of distinct pragmatic meanings. Thus, children at 0;9 and 0;11 are able to distinguish expressions of discontent and requests from responses and statements by means of prosody. Recent findings also report the use of adultlike intonational contours to convey

specific pragmatic functions in the one-word period (Marcos, 1987; for French; Prieto et al., 2012; for Catalan and Spanish).

Pointing gestures play an important role in the language acquisition process. They are grounded in joint attention, they trigger interaction, and they may also facilitate children's entry into word combination and syntax. Numerous studies have tackled this issue in the development of spoken language. The 'founding fathers' of the study of child development and language had great intuitions about the importance of gestures and their relation to language. In his notes on his son's development, Darwin (1877) stresses the importance of observing the transition from uncontrolled body movements to intentional gestures. Romanes (1889) compares human and animal gestures and makes fine observations on qualitative differences. He mentions the gestural language of deaf people as a sign of the universality of symbolic gestures. Stern (1924) considers pointing in particular as a precursor of intentional marking. For Werner and Kaplan (1963), pointing represents children's ability to discriminate between external objects and their own person. Communicational pointing then becomes the basis for referential behavior and reciprocity established in common activities between children and their parents (Bruner, 1975). As Tomasello et al. (2007, p. 720) underline, "pointing may thus represent a key transition, both phylogenetically and ontogenetically, from nonlinguistic to linguistic forms of human communication."

Not long after these first gestures produced to share attention with the adults, children engage in more complex communication and start using multimodal constructions including words. By doing so, they continue to share an intense collaborative activity, to enact roles now embodied as speaker and listener and to share conventional coordinating devices in conversation. Conversation is an activity in which the goal is to orient the listener's attention and to align intentions. The meanings expressed are constantly negotiated through dialog: adults scaffolding the children toward adult wording, children requiring clarification when they need it (Golinkoff, 1993). This takes place in communicative formats (Bruner, 1983). Linguistic interactions involve the exchange of communicative intentions through a multimodal symbolic system transmitted to children by their care-givers in daily activities and are built in the intertwining of language and action.

Children's cognitive and linguistic development centers on learning how to act and interact in the context of events, which serve as the basic unit of experience. The continuous and dynamic flow of sensation and experience is structured in terms of discrete events, which involve various participants and objects, temporal structure with a flow from beginning to end, and significant defining moments. It is the regularity and predictability of these events that allow children to master them as basic building blocks of experience; not only can they start recognizing typical and less typical examples of events, but they can gradually use them to make sense of much more complex sequences of events. They will eventually themselves learn to construct sophisticated mental structures and verbalize them. Indeed, when an event occurs repetitively in the child's daily experience, the predictable nature of the event structure provides a convenient entry point to language (Nelson, 2007). Joint parent–child action/interaction provides the scaffold for children's growing ability to grasp both what is happening around them, and what is being said in the situation. They learn to understand language and action together, each providing support for the other. The well-established language associated with simple events might provide the conceptual scaffold for the child to grasp more complex events.

A Complementary View: The Role of the Adult and the Input

Affect and Social Interaction

Tomasello et al.'s account (2005), for which cultural cognition is already founded at around 14 months, attributes complex cognitive skills to very young infants. Children's participation in interactions might be overinterpreted by scientists who could be underestimating the role of the input. For Hobson (2005), emotionally grounded sharing of experiences is primordial in order for interpersonal understanding and perspective shifting to develop. As described by Werner and Kaplan (1963), infants start from a primordial sharing situation and come to understand others' mental states as both similar to and distinct from their own, as they respond to and assimilate others' behaviors and attitudes.

Social interaction in infancy is dependent on the interplay between infants' affects, their neural learning processes, their perceptual and motor limitations and the structure of their social and affective environment. Social information helps infants decipher the meaning of others' language acts. Their drive to attend to the same objects helps them enter the language community.

Affectively valued outcomes are thought to trigger the infants' development of cognitive skills. The repetition of those outcomes facilitates the infant's attention shifting toward interesting social objects and people in the visual environment. Initially, infants prefer social stimuli such as the caregiver, but when the caregiver looks away at an object, it will habituate the infant to follow the same direction and get them attracted to other stimuli that might be positively endowed by the caregiver. The child will learn that it is often beneficial to follow caregivers' gaze shifts and learn to shift their own gaze to the same location, driven by pleasure (Triesch et al., 2006). Infants use their caregivers' emotional expressions toward objects to finely discriminate between them, something that so far, even sophisticated machines cannot do. Attention sharing will thus help children infer the mental states of their caregivers. They will use the information to shape their own communicational acts. Therefore, it is the interaction and complementarity between basic perceptual, cognitive, and affective processes that seem to trigger and guide the emergence of shared attention, which will then lead the child into symbolic communication.

When giving a bath a parent whose experience with water has been positive, who is safely holding the baby and preventing any kind of danger, whose knowledge about the sensation of the water with its right temperature provides confidence, expects the baby to enjoy the bath and its various elements. The parent can manipulate the meaning of the bath and its sensation for the child and set up a sequence of experiential histories that will provide a background for the subsequent bath experiences (Nelson, 2007). Verbal and gestural expressions convey a meaning that will come to be shared. Because they share their attention, to the same elements, that will minimize the differences between experiences (being in the bath itself as opposed to looking over the child). Sharing attention ensures that both participants experience some common

aspects of the event. Language during these experiences is an essential tool used by the caregiver to go beyond attention, and share meaning. The utterance "oh it feels so good" produced by Théophile's mother when he is 7 months old and giggling in his bath (*Paris Corpus*, Morgenstern & Parisse, 2012) makes sense of the child's individual experience and transforms it into a communal experience. It's through the repetition of the scene associated to the words that it becomes a script and that the words are transformed. In a similar fashion, Madeleine and her mother smell various flowers in their garden when the child is 11 months old (*Paris Corpus*). Mother and child are sharing sensations together; the mother actually takes the child's exact place in order to create some kind of community of sensations with her daughter. This is the basis of the building of transcendental intersubjectivity as Husserl would call it, the condition for a shared objective world and for some interdependence between those two specific individuals. Experience results from the encounter of the children with the environment, involving perception through smell, touch, taste and then action and interaction via communication. In those two examples, the children's sensations and experiences are entirely social because the adults spend considerable efforts to discern what they are feeling and thinking. However the child's experience still remains totally private, inaccessible in a way, since all the adults can do until the child expresses herself through conventional semiotic means such as gesture and speech is to make interpretations.

Adults' Interpretations

Kaye (1982) suggests that in order to understand intentions, infants must themselves be treated by adults as intentional beings. Adults must interpret their every move and action as having some meaning or some goal and provide various types of feedback to this effect. They therefore give meaning to the child's every gaze, gesture, facial expression, vocal production, projecting some kind of agency onto the infant. This begins very early on and creates the mental context for the emergence of the infant's intentional action. In the first months of life, parent–infant synchrony has a formative role in brain maturation. It was found to be predictive of children's self-regulation, symbolic play and more general cognitive skills (Feldman and Eidelman, 2004). Indeed, infants engage in 'protoconversations' from as young as 2 months old (Bateson, 1975; Trevarthen, 1974), which involve rhythmic attunement of adult and infant vocalizations. However the caregivers' role is not symmetrical as they produce amplified enhanced versions of their child's sounds (Papousek, 1989). Those exchanges are accompanied with smiles, mutual gaze, gestures that Stern (1985) has called "supportive emotional colored atunements(-*sic*)" and are therefore enriched with affect.

Parents might attribute intentionality to their infants but be deceiving themselves and contributing all the meaning in the exchange. When the child moves and seems to change her focus of attention, she might not be gazing at anything in particular, and the movement might not be intentional. However, the parent's illusion could be essential for the child's development as it bootstraps the child into our social and cultural world. Through repetition of similar situations and interpretations, the child can grow into a full-blown intentional agent.

Parents therefore seize and take up the sounds and movements produced by their children, in order to endow them with as much meaning as possible, and shape them into a form that could be compatible with the adult communicative system. In the following example taken from the Forrester corpus (CHILDES database, MacWhinney, 2000; Forrester, 2008), the father takes up his daughter's gesture, which could be interpreted as not being intentional and communicative at all, and transforms it into a game that serves as a transition toward meaning.

Example 1. Ella 1; 02

The father and the daughter are having breakfast
*FAT: Are you tired?
Ella whimpers and rubs her face.
*FAT: Oh a little bit.
She then makes a very unexpected gesture. Her hand goes down along her hair. She hits her head and looks at her father as she produces a short vocalization.
*ELLA: eh!
He takes up his daughter's gesture and points to her head
*FAT: baby's head.
He then points at his own head.
*FAT: daddy's head.

The father takes up what seems to be a nonintentional non-communicational gesture and transforms it by shaping it into a conventional pointing gesture, through which he can designate alternatively his own head and his daughter's head. He has changed it into a social gesture which is part of the string of routinely used pointing gestures of the various members of the family that Ella will take up and replay herself in the following sessions in the data.

The meaning of a large amount of communicative exchanges in general emerges from the collaborative process involved between the participants. This is even more obvious in the case of children and adults. A child might accidentally make a vocal or gestural production with no specific intention. Or she might endow it with a specific communicative intent, and not be understood by the adult. If the adult misinterprets the production, the child might refuse that interpretation but she might also accept this misconstrual and follow the adult's lead toward new directions. Conversation is therefore wholly collaborative and reanalysis of children's intentions can emerge and lead to new meanings.

Psychological states and interpretations expressed by parents interacting with children could facilitate their Vygotskyan internalization by children who simultaneously directly experience events and states and the adult's perspective on those same experiences. They therefore progressively acquire both a first- and a third-person perspective. There seems to be a collaborative engagement between adults and children in which multimodal communication and language do more than direct attention but serve as a mediation of children's mental lives and help them process complex representations (Clark, 1998). The Vygotskyan account underlines the importance of inner speech as the result of what is semiotically mediated in interaction with others. Dialogic exchanges are incorporated by the child and form inner speech. The multiple perspectives represented in dialogs or in multiparty conversations are thus internalized and construct the child as a dialogic being.

Cultural Variations

However, there are wide cultural variations in how adults interact with infants. In some cultures, adults do not treat infants as being fully intentional. Still, all typically developing children in all cultures develop an understanding of others as intentional agents. There are not enough cross-cultural studies to measure the correlation between adults' scaffolding and the development of intentionality sharing.

Ochs (1984, p. 338) argues that "the emphasis on personal intentions in Anglo society and scholarship is tied to a cultural ideology in which persons are viewed as individuals, i.e., coherent personalities who have control over and are responsible for their utterances and action s." The idea that we can have access to another person's mental life and beliefs is not shared across cultures. In the Samoan culture for instance, responsibility for people's actions is attributed to interpersonal relationships and situations.

Conclusion

The developmental path that goes from gaze following, joint attention, reading of intentions to cooperative communication including reversing perspectives expressed in the use of personal pronouns and of mental terms, involves complex connections between language, emergence of intentionality and theory of mind. Children are born into a social world in which they participate in daily conversations. In Western communities at least, adult conversationalists anticipate and explain behaviors based on desires, feelings, or beliefs. As studies based on analyses of primates as well as autistic, deaf, and typical children illustrate, the development of intentionality, of a theory of mind and of language skills therefore seem to be mutually supportive and intertwined processes.

Abstract

Symbolic interactionism (SI) is a distinctive sociological perspective that stresses the analytic centrality of investigating the meanings people give to their activities. Originating US pragmatist philosophy and its uptake by staff and students working at the University of Chicago, it developed a strongly empirical approach to social life that significantly influenced a number of substantive sociological fields, including crime and deviance, education, health and illness, organizations and work. The article elaborates SI's theoretical and methodological implications, examines its relationship to other approaches, assesses the main lines of criticism directed toward it, and describes recent developments in the field.

Symbolic interactionism (SI) is a durable and distinctive sociological perspective that stresses the importance of the meanings people give to their activities. Humans make meaning by using symbols to interpret one another's actions, and act on the basis of these interpretations. In contrast to deterministic explanations of human conduct – psychological, biological, and social structural – SI is premised on the idea that adequate understanding requires close examination of the processes of communicative interaction operating in natural (nonexperimental) social settings. This article examines SI's origins, elaborates its theoretical and methodological implications, examines its relationship to other approaches, assesses its critics, and describes recent developments in the field.

Origins and Development

SI has a complex genealogy. Herbert Blumer (1937) coined the term 'symbolic interaction' to refer to the incorporation of pragmatist understandings of human conduct into sociological investigations, in particular, those being undertaken by staff and graduate students at the University of Chicago. Blumer drew on the works of William James and John Dewey, and, above all, Chicago philosopher and social psychologist George Herbert Mead. Other important contributors to this perspective include Charles Horton Cooley whose concepts of 'the looking-glass self' and 'sympathetic introspection' became key analytical resources. Georg Simmel's studies of forms of sociation were central to the theoretical development of the Chicago tradition.

Blumer, through both his published works and his supervision of generations of graduate students at Chicago (and then, after 1952, at the University of California, Berkeley), articulated the defining features of the SI approach to social investigation. It was not until the 1960s, however, that SI became recognized more broadly as a distinctive sociological school, partly through the publication of Blumer's (1969) collected papers. Empirical applications of Blumer's ideas were undertaken by members of the 'Second Chicago School' (Fine, 1995), who owed much to the writing and teaching of Blumer's Chicago colleague Everett C. Hughes (1971). Studies by Howard S. Becker (1963), Erving Goffman (1959, 1961), and Anselm L. Strauss (1959; Glaser and Strauss, 1965) provide key examples of the application of the perspective.

Blumer's account of SI is based on three 'premises' that define its scope and mark out its distinctive analytical stance: (1) people act toward things based on their meanings; (2) these meanings arise in social interaction; and (3) conveying and changing meanings demands that people define and interpret situations.

The first premise is a rejection of the idea that 'things' have fixed and immutable meanings intrinsic to them. What an object 'means' depends on the uses to which it can be put. Thus, for instance, a brick can be part of a built structure, a weight to hold something down, or even a weapon, and its sense derives from which of these functions it is serving at the time. This approach to meaning is derived from Dewey's (1896) critique of the stimulus-response model of human behavior, in which he demonstrated that all 'stimuli' could also be understood as 'responses,' and vice versa, depending on the context of understanding.

Meaning is not, however, an individual phenomenon, but rather arises in social interaction with others, according to Blumer's second premise. Becker's (1963) account of learning to enjoy smoking marijuana provides a useful example of this. New users must *learn* smoking techniques, how to recognize the drug's physiological effects, and how to enjoy these effects, through the cues and guidance of more experienced users. Being able to have 'the same' experience on the drug depends on social interaction between novice and experienced users.

Blumer's third premise (that people must define and interpret situations) is derived from Mead's (1934) distinction between gestures and acts. While animals can gesture at one another, as when a dog growls and raises its hackles at another, this behavior is not *symbolic*. Humans, on the other hand, use symbols (especially language) to take one another's points of view, to see things as others would see them. People therefore elicit the 'meaning' of behavior by working out *why* someone is doing what they are doing, what it means to them, and responding on the basis of these attributions. These reciprocal attributions and actions *comprise* the interpreted situation.

Theoretical and Methodological Implications

Blumer's premises lead to distinctive understandings of human actors, of society, and of how these can be studied. The human agent is a reflexive self, shaping and shaped by social situations, and society is construed in associational terms, as a complex network of interactions. These implications necessitate the rejection of many of the now-conventional aspects of social theory and methodology.

Causal analyses of human actions and explanations based on structural determinism must be abandoned. Action is not 'caused,' as it is always based on the actor's interpretation of his or her situation: the situation cannot *on its own* make the actor do anything. This can be demonstrated empirically: the 'same' phenomenon will elicit radically different responses from different people (or may elicit no response at all from others), and the 'same' behavior can be elicited by all manner of different influences. A decrease in interest rates, for example, might encourage some people to spend their savings and take out loans, thereby stimulating the economy. It could also, however, have the opposite effect on others; people could quite rationally increase their levels of saving in the hopes that economic volatility could lead to more significant price falls later on.

Blumer's (1956) key statement on mainstream sociological methodology was an attack on a leading form of causal modeling, *variable analysis*. Variable analysis is the (frequently statistical) attempt to explain social organization by demonstrating relationships between different abstract concepts, for example, between the level of unemployment and the rate of crime. Measuring the two, and correlating the results, might result in the finding that an increase in one 'goes with' an increase in the other, and public policy recommendations for reducing crime could follow. Blumer identifies three problems with this popular approach. First, 'generic' variables are ill-defined and unclear. What counts as 'social cohesion,' for instance, depends on the methods of study and topic of enquiry of particular pieces of research; cohesion in a family unit, for instance, could be measured by the family members' levels of agreement on certain important issues, while cohesion in a neighborhood could be measured by how many of his or her neighbors' names each person living in the neighborhood knows. Both measure *something*, but whether this is the same thing for all respondents is unclear. Second, variables may have little connection to the setting being investigated: they may simply be imported into studies as matters of theoretical interest. Many sociological studies, for instance, are simply examinations of the distributions and inter-relationships between age, gender, ethnicity, class, and so on, in novel settings, rather than examinations of the actual relevances of parties to those settings. Variables, here, do not emerge from settings but are imposed upon them. Third, the relationship between variables – the mechanisms whereby unemployment produces lower crime rates, for instance – remain unexplored, and no amount of additional 'intervening' variables can eliminate this absence of knowledge about what exactly causes what. No one can say clearly how variables *work*.

Following the pragmatists, therefore, SI adopted a policy of *radical empiricism*, evident in a suspicion of abstract and premature theorizing, and a privileging of investigations of the real world as the best means of answering sociological questions. Theory became a tool at the service of research rather than the other way round, and concerns about cumulativity were collapsed into comparative and formal sociological tropes (Becker, 2010). As Hughes (1951: 320) argued:

> The comparative student of man's work learns about doctors by studying plumbers; and about prostitutes by studying psychiatrists … all kinds of work belong in the same series, regardless of their places in prestige or ethical ratings. In order to learn, however, one must find a frame of reference applicable to all cases without regard to such ratings … Both the physician and the plumber do practice esoteric techniques for the benefit of people in distress. The psychiatrist and the prostitute must both take care not to become too personally involved with clients who come to them with rather intimate problems.

Although symbolic interactionists use a variety of investigative techniques (indeed, one group, the Iowa School, used primarily quantitative, questionnaire-based methods), there is a preference for gathering and examining qualitative data. This derives from the earlier investigations of the 'first' Chicago School, dominated by Robert Ezra Park's (Bulmer, 1984: 97) injunction to "go and get the seat of your pants dirty in real research."

The best way to 'get the seat of your pants dirty' is by undertaking *fieldwork*, sometimes called 'participant observation' or the ethnographic study of natural settings. Becker and Geer (1957) argued that, in contrast to interviews, the other dominant method of qualitative data collection, fieldwork allows researchers to more fully immerse themselves in the situations they are investigating, and thus, better understand the meanings and roles of participants. Because it typically takes place over a longer period of time, fieldwork also allows researchers to follow meanings as they change and develop in the course of their use.

The classic statement of these emphases is by Glaser and Strauss (1967: 1):

> Most writing on sociological method has been concerned with how accurate facts can be obtained and how theory can thereby be more rigorously tested. In this book we address ourselves to the equally important enterprise of how the discovery of theory from data – systematically obtained and analysed in social research – can be furthered. We believe that the discovery of theory from data – which we call *grounded theory* – is a major task confronting sociology today, for, as we shall try to show, such a theory fits empirical situations, and is understandable to sociologists and laymen alike. Most important, it works – provides us with relevant predictions, explanations, interpretations and applications.

Relationship to Ethnomethodology and Mainstream Sociology

SI's closest sociological relative is ethnomethodology (Garfinkel, 1967). Both are suspicious of premature theorizing and seek to minimize any theoretical framework to no more than is required to facilitate studies (Blumer, 1969;

Sharrock and Anderson, 1982). Both favor qualitative methods, in particular ethnographies (Becker and Geer, 1957; Garfinkel, 2002: 248). Both reject the idea that there can be an 'objective' description of social interaction: for ethnomethodologists the meaning of any action is reflexively tied to its context, with action, sense, and situation mutually elaborating one another *in situ* (Garfinkel, 1967: 3–4).

There are, however, also significant differences. These come to a head in the relationships between each perspective and mainstream sociology: practitioners of SI argue that theirs is a *better way of doing sociology*, while ethnomethodologists understand their work to be *an alternative to it*. The former have argued that their perspective addresses glaring errors in conventional sociological approaches to research (Blumer, 1956). The latter argued that their approach constitutes an 'asymmetrical' and 'alternate' sociology *tout court*, in which nothing is sacred, and even the most fundamental sociological concepts must be 'respecified' (Garfinkel, 2002: 114–120).

Mainstream sociological work has itself, over the last 20 years or so, increasingly engaged with themes central to the SI tradition. This has typically been unattributed, however, and the perspective itself is often misrepresented both in textbooks and in teaching. As Maines (2001: *xv*) points out, "sociologists over the years have learned a way of talking about themselves and their discipline … that has compartmentalized interactionist work and relegated it to the margins of scholarly consideration while simultaneously and unknowingly becoming more interactionist in their work." We shall now turn to the mainstream response to SI.

Criticisms

The conventional sociological view of SI is that it neglects considerations of both power and social structure. It is regarded as a perspective holding an unduly optimistic vision of the open society that is blind to the workings of various forms of institutionalized constraint and inequality. These criticisms miss the subtlety of some of the key statements in SI. Rather than neglecting the workings of power, SI studies show how power is manifested in everyday situations; rather than neglecting social structure, SI investigates social structure *in statu nascendi* as Simmel used to put it.

Research on deviance is perhaps the best-known area of interactionist work, particularly following the enormous success of Becker's (1963) *Outsiders*. Such work has led to a greater appreciation of the perspective of the deviant, the marginalized, the stigmatized, and from time to time such studies have contributed to political and institutional reforms. Yet the focus on the responses – both individual and collective – of those who are 'labeled' in various ways has all too often served to obscure the primary, and arguably more fundamental, concern of interactionist studies with the *authoritative* processes through which individuals are rendered subordinate through legally sanctioned and institutionally established procedures.

This approach can be understood to develop Durkheim's (1984) ideas about the cultural variability of laws and norms. Whereas Durkheim saw 'crime' in terms of those acts that offend the basic values or 'collective sentiments' of a society or group, SI seeks to avoid the reification of 'society' intrinsic to this kind of formulation. Its focus, instead, is on how actual rules are established, enforced, challenged and broken, often in situations where cultural consensus cannot be assumed:

> … laws and rules represent no group's values nor values of any portion of a society. Instead they are artefacts of compromise between the values of mutually opposed, but very strongly organized, associations.
>
> Lemert, 1972: 57

SI does not neglect power relations, but argues that they are the product of interaction rather than supra-individual 'structural' forces. Becker made this essential point clearly, starting with the Durkheimian theme that *social groups create deviance by making the rules whose infraction constitutes deviance* (Becker, 1963: 9, emphasis in original), then making explicit the sociological corollary that "deviance is *not* a quality of the act that the person commits, but rather a consequence of the application by others of rules and sanctions to an 'offender'" (Becker, 1963: 9, emphasis in original).

This position fully recognizes that there are patterns to such applications of rules. Becker (1963: 17–18) goes on to state:

> Who can, in fact, force others to accept their rules and what are the causes of their success? This is, of course, a question of political and economic power … Rules are made for young people by their elders … Men make the rules for women in our society … Negroes find themselves subject to rules made for them by whites. The foreign-born and those otherwise ethnically peculiar often have their rules made for them by the Protestant Anglo-Saxon minority. The middle class makes rules the lower class must obey – in the schools, the courts, and elsewhere … Differences in the ability to make rules and apply them to other people are essentially power differentials (either legal or extralegal). Those groups whose social position gives them weapons and power are best able to enforce their rules. Distinctions of age, sex, ethnicity, and class are all related to differences in power, which accounts for differences in the degree to which groups so distinguished can make rules for others.

The point is not that there are patterns of inequality and domination in society, a point with which symbolic interactionists would not disagree. Rather, the issue at hand is *through what mechanisms* are those patterns produced and reproduced. Here work such as Cicourel's (1968) examination of how police officers define the actions of black youths as 'threatening' while treating the 'same' actions are 'high spirits' when undertaken by their white counterparts is important. The discovery of a pattern of inequality animates studies of *how that pattern is generated* rather than representing the conclusion of a sociological investigation.

Developments

SI was always a tradition more varied than Blumer's guiding statements suggested. Not all symbolic interactionists subscribed to Blumer's views. An early division was identified between the Iowa School and the Chicago School of SI: the

former emphasizing structure and conventional social scientific precepts, the latter stressing process and negotiation and preferring qualitative methods. The Iowa group used self-report measures such as the Twenty Statements Test and favored an approach that did not place SI in opposition to standard scientific conceptions. Its leading proponents, including Manford Kuhn and Carl Couch, accepted more of the 'facts of social structure' (Stryker, 1980: 1) than the Chicago-oriented group. While the Chicago version of SI has predominated, there were disputes around the precise character of Mead's legacy. In particular, it was contended that Blumer's advocacy of qualitative methods at the expense of conventional social scientific procedures could not be legitimated by Mead's views. The dominance of the Chicagoan version of SI led some commentary to elide the notions of Chicago sociology, ethnographic research, and SI. Against this, it is important to remember that SI was not the only theoretical stream in Chicago's famed sociology department.

More recently SI addressed debates originating from cultural studies and postmodern and poststructuralist trends about how culture can be most adequately represented. Again, generalizing somewhat, there are differences between those who favor some form of realism, with an emphasis on fieldwork traditions of cultural description, and those who seek to pursue constructionist arguments to the point where questions about inscription – the deskwork ethnographers do to produce to their ethnographic analyses – precede all others. On both sides the question of representation, the sense that readers make of the texts that mediate culture to an audience, becomes salient (Van Maanen, 2011).

The development of the SI spawned a rich and diverse range of studies connected by an analytic commitment to articulate people's ordinary experience of the world. It long stood as a productive alternative to functionalist and structural sociologies. Interactionist ideas have significantly impacted upon a number of established sociological fields, such as crime and deviance, education, health and illness, organizations and work (see Atkinson and Housley, 2003; Fine, 1993; Reynolds and Herman-Kinney, 2003 for reviews).

SI has illuminated public issues. Interaction is central to understanding how some social condition comes to be defined as a social problem. This is an often contested matter where groups advancing competing claims (Spector and Kitsuse, 1977) about the characteristics of the problem use a range of resources – material, symbolic, and political – to persuade publics and legislators of the legitimacy of their definitions (Holstein and Miller, 2003). Here Goffman's (1974) frame metaphor has proved enormously influential in analyses of how issues and problems are defined as such.

SI played a major part in opening up new fields, notably the sociology of emotion (Hochschild, 1983) and the sociology of public places (Lofland, 1998). People's experienced emotions are intimately connected to situated interaction. Emotions are not simply biological and psychological phenomena; they are socially organized by 'feeling rules' enacted in contexts of everyday interaction. Similarly, the investigation of public places has shown that the conduct there is far from asocial. Goffman's (1983) work on the 'interaction order' demonstrated how public places are delicately ordered by local rules that regulate territoriality, civil inattention, forms of regard for the other, the expression of information about the self, and the like. W.I. Thomas's famed apothegm that if people define things as real, they are real in their consequences, justified the close study of subjectivities and catalyzed a series of interactionist-inspired studies of ordinary action. Goffman's (1974) frame analysis offered a systematic and admittedly formalistic answer to the fundamental practical problem, "what is it that is going on here?"

Ethnographic research addressed the same question more discursively and with attention to the empirical details of situated symbolism and the emergent meanings arising in natural social settings. Directly or indirectly, ethnographic studies have drawn upon the SI tradition, seeking new ways to uncover and represent the 'actor's point of view' – the experience of people as they go about their daily lives. New standards of the intensity and extensiveness of ethnographic investigations have been set, clearly marking out such work from jibes about 'tenured journalism' (Fine, 1993). Observation of people's activities over extended periods of time is one feature of interactionist-inspired ethnographies of Black American inner-city street life – Anderson (1990) was the result of 14 years' research. Anderson's (1999) subsequent book also drew on that fieldwork and another 4 years of ethnographic research in poor and well-to-do neighborhoods. Duneier's (1999) ethnography of street vendors was based on more than 3 years' fieldwork. Duneier's study was also notable for his close collaboration with his key informant and a noted photojournalist, for its pioneering audio recording of street encounters, the quasi-legalistic standards of evidence and proof applied to analytic inferences drawn, and the sharing of the financial proceeds of the book with the research participants. Similarly, Alice Goffman's (2014) study of young black parolees was based on 6 years of immersive fieldwork. Studies such as these exemplify the sustained commitment of ethnographers to depict accurately the viewpoints of research participants and to entertain seriously inconvenient facts.

Over the past quarter of a century SI has proved a tradition remarkably open to postmodern and post structuralist critiques and developments in the social sciences and humanities, including cultural studies (Becker and McCall, 1990). Several aspects of these intellectual shifts are incorporated into SI by Denzin's (2001) 'interpretive interactionism,' which explores new ways of making people's problematic experience available to the reader by artistic and social scientific methods. The examination of people's reflections about these problematic experiences ('epiphanies') was also pursued by autoethnography, a method where the ethnographer explores their own personal experience (see Ellis et al., 2010 for a review of controversies about the method). Autoethnography has proved especially effective in conveying the personal and cultural meanings encountered in challenging situations, such as facing life-threatening illnesses (Frank, 1991) or learning to become a competition-standard boxer (Wacquant, 2004).

Appraisals of SI's future (Fine, 1993; Maines, 2001) have noted its distinguished past but, prudently, have been ambivalent about its future. The SI tradition has expanded, diversified, and become internationalized. There is an important sense in which it has become mainstream and is no longer

a 'loyal opposition.' As Atkinson and Housley (2003) put it, "we are all interactionists now." Well, perhaps. SI's abiding appeal is likely to continue to be its resolutely empirical approach to the social organization of people's experiences.

Intercultural Communication: An Anthropological Perspective

Pál Nyíri, Vrije Universiteit, Amsterdam, The Netherlands
Joana Breidenbach, Betterplace Lab, Berlin, Germany

Abstract

This article is a critical review of intercultural communication (IC), an applied academic field whose goal is to understand how members of different cultural – usually national or ethnic – groups communicate, behave, and perceive the world, as well as to facilitate communication between them. The article traces the history and current state of IC, both as an academic field and as a service industry; examines the concepts of culture upon which its assumptions rest; and offers a critical perspective on its usefulness and limitations.

Intercultural communication (IC) is an applied academic field with applications particularly in management, education, and health care. It seeks to understand how members of different cultural – usually national or ethnic – groups communicate, behave, and perceive the world in order to facilitate communication between them. In academic institutions, IC is usually taught as part of courses in communication studies, management, or languages, and sometimes as a separate field of study. Outside academia, companies offer consultancy and trainings in IC, publishing houses specialize in IC texts, and business magazines run IC columns. The clients of IC consultancies include corporations, government institutions, hospitals, and militaries.

Origins

The term 'intercultural communication' was used in anthropologist Edward T. Hall's best-selling 1959 book *The Silent Language*, regarded as the 'founding document' of the field (Rogers et al., 2002: p. 11). At the request of the Foreign Service Institute, Hall developed a practical approach to sensitize future diplomats to cultural differences that obstruct communication. He divided societies into those with high vs low 'context,' those with 'monochronic' vs 'polychronic' time systems, those with higher and lower needs for personal space, and those with higher and lower speed of messages (referring to the formation of social networks). 'Low context' societies were those where people compartmentalized interaction in various personal and professional settings, and since that meant having less background knowledge about those outside their immediate circle of relatives or friends, they required more information to complete a task. (Thus, a Chinese employee could be given much simpler, verbal instructions than an American because the intense social interaction between manager and employee would create much tacit understanding between them.) Similarly, a 'monochronic' time system meant a compartmentalized management of tasks – where scheduling and precision punctuates the natural rhythm of human interaction, distinguishing work time from leisure – while 'polychronic' referred to dealing simultaneously with a range of matters and people and to a greater tolerance of delays.

Hall's views were inspired by the Culture and Personality School of Anthropology that flourished at Columbia University in the 1940s and 1950s, and included Margaret Mead and Ruth Benedict, as well as by Freudian psychoanalysis and the Sapir-Whorf school of structural linguistics (Rogers et al., 2002: p. 5). As Mitchell Hammer, an intercultural trainer, wrote, anthropology at the time described "patterns of human interaction as it exists within a particular group of people and within another group." In Hammer's view, Hall's innovation was to look at the interaction between human groups: "that's what intercultural communication was about" (Dahlén, 1997: p. 102).

Hall was the first to call the attention of nonanthropologists to the culturally constructed nature of ideas about time, privacy, and nonverbal communication. He did not offer simple, quantitative matrices to apply to the societies he described and did not explicitly divide the world into regions colored differently based on whether they were, for example, 'high or low context.' He also did not regard IC as a separate academic field. But Hall's description of culture as a 'silent language,' a code that could be cracked and taught; his use of untranslated concepts from the Japanese, which had an exoticizing effect; his general statements about 'the Americans' and 'the French'; and his insistence that 'like oil and water, the two systems' (monochronic and polychronic time) 'do not mix' lay the groundwork for the conceptual framework of the field of IC as it emerged in the 1960s and 1970s. The first IC textbook was published in the United States in 1966, and the Society for Intercultural Education, Training, and Research, which remains the leading international body of IC, was founded in 1974.

In the 1980s, IC incorporated concepts and methods taken from social psychology, a discipline that relies on the quantitative analysis of large-scale opinion surveys and on controlled experimentation in laboratory settings, and cross-cultural psychology. Cross-cultural psychology, a subfield of social psychology that acquired its own identity in the early 1970s, proceeds by identifying a number of universal dimensions of behavior, such as individualism or respect for authority, and tests them comparatively across different groups, revealing quantitative variations in reactions to particular situations through statistical methods such as factor analysis. For example, Harry Triandis, a psychologist with major influence in IC, described 'cultures' on value scales such as 'tightness,'

individualist vs collectivist, vertical vs horizontal, active vs passive, universalist vs particularist, diffuse vs specific, instrumental vs expressive, and emotionally expressive vs suppressive (Triandis, 1994). Such sets of cultural variables are sometimes derived from cross-national surveys, but very often they are simply postulated. In other words, while cross-cultural psychology generally assumes that particular cultures (i.e., nations or ethnic groups) can be distinguished by core sets of values, it is interested not in establishing what these values might be (and hence, whether they indeed form a coherent set or not) but in how behavior varies across what are assumed to be cultures driven by different values.

Key Concepts

The most-cited IC study is Geert Hofstede's survey of work-related values among 88 000 IBM employees in over 50 countries, conducted between 1967 and 1973 and published as *Culture's Consequences* in 1980. Claiming that "data obtained within a single MNC [multinational corporation] does have the power to uncover the secrets of entire national cultures" (Hofstede, 1980a: p. 44), Hofstede, trained as a social psychologist, proceeded to develop a system of 'cultural dimensions' that identifies and quantifies 'value orientations' – a concept originally developed by Kluckhohn and Strodtbeck (1961) – in different societies. In a frequently quoted definition, he saw culture as "the collective programing of the mind that distinguishes the members of one group or category of people from others" (Hofstede and Hofstede, 2004: p. 4). This 'programing' is acquired through socialization in a particular country (Hofstede, 1980b: p. 14).

The six cultural dimensions, measured on a scale from 0 to 100, are 'power distance,' collectivism–individualism, masculinity–femininity, uncertainty avoidance, long/short-term orientation, and indulgence–restraint. (Hofstede added the last two later.) To focus on one of these variables, the 'collectivism' dimension means an orientation toward the expectations and norms of the we-group (such as kin) and strict differentiation between it and outsiders. By contrast, in individualistic societies, individuals are expected to be concerned primarily about themselves and their immediate family members, and the distinction between the in- and the out-group is weak. 'Power distance' denotes acceptance of hierarchy vs preference for egalitarianism. Thus, Americans are individualists with a small power distance; Chinese, collectivists with a large power distance.

Another influential IC author and consultant, Fons Trompenaars, uses seven rather than six 'cultural dimensions' (see Table 1). Trompenaars' study, published in his book *Riding the Waves of Culture*, was based on a questionnaire administered in 1993 to 15 000 managers and administrative staff working in corporations in 50 countries. He found that Americans and Europeans are 'universalistic' while Chinese are 'particularistic.' This is because Westerners think in a logical and linear fashion and make sense of the world using abstract concepts. Chinese thinking, on the other hand, is intuitive, nonlogical and nonabstract. Dutch and Swedes are 'neutral' because they consider the control of emotions as a sign of civilization and deem it inappropriate to exhibit them in work relations, whereas Southern Europeans are 'affective' because they show their feelings openly in the workplace as well as at home.

Table 1 Trompenaars Hampden-Turner's 'seven dimensions of culture'

>>>Universalism vs Particularism
What is more important – rules or relationships?
>>>Individualism vs Communitarianism
Do we function in a group or as an individual?
>>>Specific vs Diffuse cultures
How far do we get involved?
>>>Affective vs Neutral cultures
Do we display our emotions?
>>>Achievement vs Ascription
Do we have to prove ourselves to receive status or is it given to us?
>>>Sequential vs synchronic cultures
Do we do things one at a time or several things at once?
>>>Internal vs External control
Do we control our environment or work with it?

Not all IC authors use Hofstede's or Trompenaars' categories, but most popular IC texts (Chaney and Martin, 2004; Gudykunst and Kim, 2002; Jandt, 2006; Lustig and Koester, 2005; Martin and Nakayama, 2003; Samovar et al., 2009; Varner and Beamer, 2005) operate with a similar set of dimensions and values. In the late 1980s, academic and corporate interest in the so-called 'Asian tigers' led to a shift in focus to Asia in the work of IC theorists. Taiwan, Hong Kong, and Singapore had all scored high in the dimensions of Collectivism and Power Distance in the Hofstede survey, but the base in both Singapore and Hong Kong had been too small for statistical analysis. A Chinese Values Survey, conducted in 23 countries by social psychologist Michael Harris Bond in consultation with Hofstede and scholars from Hong Kong and Taiwan, confirmed Hofstede's earlier findings and, additionally, came up with a set of values described as Confucian Dynamism, on the basis of which Hofstede developed the dimension he called long-term orientation. Confucian Dynamism entailed a long list of values, including persistence, industriousness, benevolent authority, loyalty to superiors, harmony with others, wealth, pragmatism, thrift, wealth, patience, respect for hierarchy and tradition, protecting 'face,' resistance to corruption, family orientation, high work morale, and patriotism (Bond, 1986: pp. 9–10). In a subsequent article, Hofstede and Bond (1988) directly linked Confucian dynamism to economic growth.

By the late 1990s, the interest of some IC theorists and practitioners began shifting away from determining group characteristics and toward measuring, and, through various trainings, expanding 'cultural' or 'intercultural competence,' a set of skills that defines an individual's ability to work with cultural difference. The Intercultural Development Inventory, developed by Milton J. Bennett and Mitchell Hammer, for example, locates individuals at one of the six stages of intercultural sensitivity, from 'denial' to 'integration' of cultural difference, on five different scales corresponding to particular cognitive mechanisms. Leading authorities on diversity management such as

Taylor Cox, Jr., tend to focus on differences in perception, influenced by the relative social status of two individuals as much as their 'core values.' Thus, Cox (1994: p. 142ff) discusses the differing evaluation of a promotion policy by black and white American employees in a company and interprets them primarily as a result of minority–majority power dynamics. Nonetheless, Cox's discussion of culture relies on 'dimensions' as developed by Hofstede, Hall, Bond, and others.

Applications

IC consultancies provide their services to both large and small businesses, as well as government institutions. Typically, these take the form of trainings or tests, often built on a 'critical incident,' a situation in which unrecognized cultural difference causes a breakdown in communication. Most trainings are specific to a particular national culture – in the context of a relocation, merger, or negotiation process – and provide clients with a compass or kit, often based on Hofstede's or Trompenaars' dimensions. Trainings that focus on cultural sensitivity place less emphasis on 'cracking cultural codes' and more on making individuals aware of the diverse factors that influence the behavior and judgment of both their business partners and themselves. These factors may include socioeconomic status, family history, or individual psychological traits.

Public health has been a major customer of 'cultural competence' trainings in North America since the 1990s, influenced not only by a concern with inequalities in health indicators and access to health care, but also by anthropological perspectives on the cultural contexts of health and illness. Medical anthropologist Arthur Kleinman (2004: p. 951) summed up the new public health paradigm as recognizing that "culture influences the experience of symptoms, the idioms used to report them, decisions about treatment, doctor–patient interactions, the likelihood of outcomes such as suicide, and the practices of professionals." This paradigm fitted in a broader trend toward 'patient-centered care.'

The U.S. Liaison Committee on Medical Education implemented a standard for cultural competence in 2000, defining it as the requirement for "faculty and students [to] demonstrate an understanding of the manner in which people of diverse cultures and belief systems perceive health and illness and respond to various symptoms, diseases, and treatments," as well as "to recognize … gender and cultural biases in health care delivery" (Association of American Medical Colleges, 2005: p. 1). In 2004, a report to the British government recommended mandatory cultural competence training for all managers and clinical staff at mental health institutions. Generally, 'cultural competence' programs and manuals endeavor to accomplish three aims: to provide information on particular 'racial' or ethnic groups, their health status and their traditions of medicine; to provide practical information on matters ranging from diet to mourning customs; and to increase the cultural sensitivity of practitioners.

A large number of trainings, especially in Europe, focus on Muslim patients. While some medical organizations warn against group stereotyping and emphasize the need for sensitivity to individual differences, most manuals are "primarily lists of characteristics for particular races and ethnic groups" (Lee and Farrell, 2006: p. 9) and treat individuals as carriers of these collective traits.

The Context of IC's Rise and Global Spread

As evidenced by the Library of Congress' holdings, publications in IC first appeared in the 1950s, and their number has since grown exponentially (Piller, 2011: p. 30). As Piller notes, the rise of IC in the United States corresponded to "the rise of a US perception of the world in terms of international competition and threat" (*ibid.*: p. 33). The Foreign Service Institute, where Edward Hall worked, grew out of a set of training programs for military personnel during World War II (*ibid.*: p. 31). In the late 1960s and 1970s, the spread of IC was mostly fueled by the emergence of Japanese companies as competitors to American ones. A Japanese translation of Edward Hall's *The Silent Language* was published as early as 1966, and universities established IC departments.

From the following decade on, the growth of IC has been increasingly linked to the emergence and spread of the contemporary multinational corporation. By the time SIETAR, the Society of Intercultural Education, Training and Research, was founded in the United States in 1974 (the first SIETAR branch outside the US was set up in Japan in 1985), an increasing number of – mostly American – businesses were operating multinationally: relying on markets or suppliers in countries other than where they are headquartered; having ethnically diverse and geographically dispersed workforces; and engaging in mergers and acquisitions abroad.

In the 1990s, with worldwide market deregulation, the global spread of consumption patterns, and the fragmentation of the production process including the outsourcing of back-office work, the globalization of corporations took on a new scale. In addition, dealing with cultural difference became part of management tasks, both in product development and marketing, and in personnel management. By the end of the decade, ethnic diversity of the workforce became both a mainstream political and often legal expectation in North America and Western Europe and a management fad. Today, large companies expect their employees to understand markets, consumer behavior, and workplace relations across borders. Meanwhile, they are confronted with the cultural pluralization of their workforce as well as their shareholders. Cultural difference, seen in the early 1990s as a technical obstacle to maximizing productivity, that good management should overcome, is nowadays often considered an asset that nonetheless should be properly managed.

Meanwhile, due to both management and policy trends that included a more explicit approach to ethnic diversity, IC took root in Europe (a SIETAR branch was established in 1991). IC chairs have been established at several European universities, and the subject of 'IC' has even become part of the German school curriculum. SIETAR branches were established in India in 2006 and in the Middle East in 2007, signaling the growing emphasis on global business in these places. Books by Hofstede and Trompenaars are now used to teach students from Chemnitz Technical University in eastern Germany to Hosei University in Japan and King Saud University in Saudi Arabia. More broadly, the continuing spread of IC is buoyed by the

currency of cultural explanations to account for a wide range of international, corporate, social, and personal conflicts in the post-Cold War world (Breidenbach and Nyíri, 2009).

Critique

A popular reader in IC now in its 12th edition defines culture as *the rules for living and functioning in society* (Samovar et al., 2009: p. 10, emphasis in original). It goes on to state that "cultural identity is derived from our 'sense of belonging to a particular cultural or ethnic group,'" that "*culture is learned*" and that "*culture is transmitted intergenerationally*" (*ibid.*: p. 11). Mainstream IC understands the world as a mosaic of distinct national societies, each of which has a set of rules that are, at their core, resistant to change. In an oft-quoted 'model,' Trompenaars compares cultures to onions (Trompenaars and Hampden-Turner, 1998: p. 6). This national cultural determinism is the main conceptual weakness of mainstream interculturalism. It reflects the inheritance of anthropology before the fundamental changes of the 1970s and the 1980s, when – as Clifford Geertz famously wrote in 1973 – it began seeing itself no longer as "an experimental science in search of law but an interpretive one in search of meaning" (Geertz, 1973: p. 5). A decade later, in a book that was hugely influential for the subsequent direction anthropology took, James Clifford turned radically against the culture concept Edward Hall had used: culture, he wrote, was "neither an 'object to be described' nor a 'unified corpus of symbols and meanings that can be definitively interpreted'" but "contested, temporal, and emergent" (Clifford, 1986: pp. 13, 19). Cultural anthropologists now broadly agree that cultures previously depicted as static and monolithic entities have in fact always incorporated outside influences, and that beneath their facades of homogeneity lie conflicts between individuals and groups who had quite different views on and uses for common cultural practices.

Similarly, linguistics "have long since moved away from structuralism with its emphasis on discrete units" (Piller, 2011: p. 32), which defined Hall's approach and continues to be influential in IC. Some cross-cultural psychologists have also been critical of national cultural dimensions failing to pay attention to individual variation, power structures, conflicts within groups, and historical change (Gjerde, 2004).

The empirical basis of mainstream IC's national typology is also problematic. Hofstede's IBM study – one of the discipline's foundational texts – was done on a relatively small sample in most of the included countries: only in six countries (five of them in Western Europe) did the number of respondents exceed 1000. Numerous other surveys have come to conclusions in direct opposition to Hofstede's making; one found that, among respondents in Japan, Korea, Taiwan, and Denmark, 'hard work' was least important for the Japanese, 'creativity' was rated highest in Korea and lowest in Denmark, and 'obedience' was more important for Danes than for any of the Asians (Helgesen, 2001). Aside from sampling problems, such inconsistence shows that questionnaires and formal interviews reflect how people see themselves and want to be seen by others, not how they actually behave. Surveys also fail to capture the influence of politics and the historical moment on *both* what people say and what they do. Cultural dimensions, postulated as an unchanging core, are ill-equipped to deal with change, whether political, social, or organizational. In the context of health care, where the focus is often on migrants, critics point out that the cultural 'trait lists' (Kleinman and Benson, 2006) rely on frequently antiquated descriptions of societies of origin, to the point where doctors are sometimes misled into looking for a cultural rationale where there is none.

IC studies that deal with differences between organizational cultures more often produce useful insights because they operate on a tangible scale of day-to-day encounters and allow to see how individuals deploy cultural difference (or similarity) strategically to achieve their aims. Yet even where the intention is to sensitize people to dealing with cultural difference (and its conscious manipulation), IC trainers often fall back on the schematic world of 'cultural dimensions.' For example, a study of US–Mexican joint ventures showed that, contrary to predictions made on the basis of Hofstede's and Trompenaars' dimensions, Mexican workers welcomed participatory management techniques introduced by the Americans, but attempts to explain these reactions within the framework of those dimensions (Rao and Teegen, 2001).

Recent Developments

Some IC scholars and practitioners are critical of the 'dimensions' approach. Alois Moosmüller, a professor of IC at the University of Munich, points out the danger of seeing culture as primordial and has devoted research to the effects of national stereotyping in German–Japanese joint ventures (Moosmüller, 2000). A more radical revisionist movement within IC has come from sociolinguistics and discourse analysis. In an IC textbook published in three editions since 1995, Scollon et al. (2012) focus on 'discourse systems' rather than 'cultures' that exist prior to discursive construction. They point out that all communication is in a sense 'intercultural,' that the 'culture' in question depends both on the multiple situatedness of individuals in various social categories and on their choice of which available discourse to deploy, and that 'avoiding miscommunication' requires an understanding of the situations from which individuals speak. In another critical text, Ingrid Piller (2011: p. 2) points out the paradox that the culturally 'pure' cast of characters IC usually operates with, does not reflect the profiles of most IC practitioners or learners. Following critics such as Brendan McSweeney (2002), Piller (2002: pp. 77–83) sees the work of Hofstede and his followers as conceptually unsound, practically useless (because of its inability to account for the internal heterogeneity of societies: an IC training on doing business with Germans would have no place for the 60 000 German businesses owned by ethnic Turks, for example) and morally reprehensible (because it reinforces stereotypes). She proposes a re-orientation of IC from its central preoccupation with group characteristics to a "material-linguistic" focus on "Who makes culture relevant to whom in which context for which purposes?" (Piller, 2011: p. 172).

Studies in this vein of IC use ethnographic or discourse analysis approaches. Some find that conflicts or

misunderstandings attributed to cultural difference stem not from ethnic fault lines but from conflicts of interest or differing central values held by subgroups within an organization, as in the case of a high-tech company operating in Germany and India (Mahadevan, 2007). Other studies focus on the consequences of language policy choices within multinational companies for relations between employees (Piller, 2011: pp. 86–87). While such studies may reflect the complex causes of conflict more accurately, it is as yet unclear whether they can take the place of Hofstedean approaches, which appear to provide easy and affordable answers to existing corporate needs.

Intercultural Legal Discourse: Philosophical Aspects

Otfried Höffe, Universität Tübingen, Tübingen, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article focuses on the concept of intercultural legal discourses on morality, justice, and law. These discourses demand that other cultures are to be taken seriously in their own distinctiveness. Nevertheless, this does not lead into relativism. Instead, these intercultural discourses take on a universalist point of view while retaining an ethics of respect toward different cultures. To provide an example for such a discourse, the article examines the question if there is an intercultural criminal law.

The Basic Idea

The intercultural discourse on morality, justice, and law is neither limited to a particular society, nor is it committed to certain presuppositions prevalent in a single society. The practice of intercultural discourse, rather, opposes the danger of judging other cultures with the values and standards of one's own culture (ethnocentrism). This danger is especially present in the tendency of devaluing other cultures from the standpoint of European and American cultures in judging them to be deficient, primitive, barbarous, or underdeveloped (Euro or Americocentricism). Basic approaches to an ethics of respect for other cultures can be found in Herder's concept of "a people's genius" ("Genius eines Volkes") and in Hegel's theory of "people's spirits" ("Volksgeister"). Subsequently, through the course of history, different forms of culture are being developed, which are coherent and, thus far, justify themselves.

The intercultural discourse demands that other cultures be taken seriously in their own distinctiveness. This, however, does not imply relativism. There are numerous causes as to why intercultural discourses are needed. To name but a few: the challenge of pluralism, globalization in all its facets, the growing self-consciousness of various cultures, and the worldwide migratory movements. Heuristically speaking, the basic idea of the intercultural discourse can be formulated as follows: Whatever we consider to be fundamentally important, we can expect to discover in different cultures, too. This basic idea works positively – what we consider to be basic justified claims can be found in other cultures, as well – and negatively: Whatever we consider to be blameworthy, other cultures do so, too.

An intercultural discourse of morality, justice, and law takes place on several levels:

1. Within the history of moral and legal thought, the intercultural discourse tries to uncover the origin of morality and law distinctive to different cultures, and the various cross-cultural influences. Thus, the intercultural discourse points to the fact that even the oldest European faculties of law are influenced by Islamic thought. Islamic thought, in turn, is informed by ancient Greek moral, legal, and political thought. And these intercultural influences stretch even further back into history: Remember, for example, that Solon, the great legislator of ancient Greece, traveled through numerous countries; that Plato takes other city-states, for example, Sparta, as a paradigm; and that Aristotle praises Carthage's constitution, which is not Greek.
2. In comparing different legal cultures, the intercultural discourse focuses on the shared moral legacy of mankind such as the Golden Rule, basic procedural principles, universally accepted legal goods, and fundamental principles of justice. Furthermore, it recognizes that in all cultures character-traits such as integrity and righteousness, bravery, and helpfulness are highly esteemed.
3. In the justification of moral and legal principles, the intercultural discourse does not recourse to premises that are particular to a given culture, but instead uses universally valid premises that are founded on human reason and in anthropological elements. The intercultural discourse considers those arguments as valid that cannot be rejected from the viewpoint of any culture. It employs a basic distinction between universality and uniformity. Against communitarian objections, it defends universally valid principles that are justified in a formal way, thus securing openness for the distinctiveness of different cultures. It focuses on normative principles for the regulation within one society as well as on principles that should govern the interaction between societies.
4. Concerning moral and legal practice, the intercultural discourse demands that the principles be realized cautiously: Other cultures should be allowed to go through similar learning processes in due time that Europe and North America have been through with regard to human rights and international law.

An Example: Is There an Intercultural Criminal Law?

The Question

The still ongoing process of globalization reaches far beyond economical and financial issues. In the course of this process, social and cultural borders are frequently transgressed. Therefore, we need to address the question how legal orders should react toward strangers, especially toward those strangers coming from an essentially different legal culture: May legal orders use their strongest means, that is, criminal law? Do they possess a (subjective) right to use their (objective) criminal law cross-culturally? Is there an intercultural right to punish persons?

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63105-7

These questions are all the more urgent since globalization threatens an element that is indispensable for human beings: the attachment to well-defined groups. It is not just the well-being of persons that is thus endangered, but the specific kind of personal identity that relies on such fundamental legal goods as the right to one's own religion, one's own language, and one's own culture. Even where these goods are not threatened directly, an indirect danger lurks: The stranger, coming from another culture, for a long time will feel "culturally torn" between the older and the new (legal) culture. From a criminal-political point of view, this situation is highly relevant: Persons whose identities are aggrieved tend to be more criminally active than those who have a stable identity.

In a much less dramatic way, these questions arise from another perspective as well: Almost all legal cultures acknowledge that legal authority should reside with the state. Furthermore, they also share the recognition of a great amount of types of criminal offenses. And ever since the Code of Hammurabi (*c.*1770 BC) was written down, we have the information that legal goods like life and limb, property, and a good name ("honor") have been legally protected since the ancient times. Now if, first, the same acts are regarded as criminal offenses, and, second, if it can be expected by the stranger to inform himself at least with regard to criminal law about the peculiarities of his host country – especially within such realms in which peculiarities are to be expected – he cannot easily appeal to cultural variations.

Five Types of Answers

Whoever is aware of the course of history knows that the question about international criminal law is in fact not as new as might be suggested by the extent to which many contemporaries praise the connection between globalization and multiculturalism as the newest accomplishment of mankind. On the one hand, one should not forget that the problems in question already occur within a single pluralistic society: The so-called old European states have gone through a process of differentiation starting with the Reformation, affirmed by the Enlightenment, and reinforced by the Industrial Revolution. Within this process of differentiation, the relatively homogenous cultures were dissolved and multidimensional and open societies were created. In these societies exist a still-growing number of different groups with their own interests and convictions, and thus various values, manners, and life-styles. As far as it was necessary, during the course of history criminal law adapted quickly to the new circumstances via a process of liberalization: No matter whether you adhere to a different religion or whether you are an atheist, no matter whether you criticize the society or the government, no matter whether you want a divorce or whether you are homosexual – all such "deviant" behavior is no longer a criminal offense, but instead is considered irrelevant from the perspective of criminal law.

On the other hand, it is necessary to point out that accounts of multiculturalism and even globalization have a long tradition themselves: Think, for example, of what happened in the vicinities of Alexander the Great's campaigns; of the growth of the Roman Empire; of the spread of Christianity and of Islam. Last but not least, we are aware of these kinds of developments during the Age of Discovery, the Age of Colonialism and of Industrialism, and the Age of World Trade. Within all those developments, the same question arises: How to treat a stranger in cases of criminal law? From ancient times onward, certain types of answers to this question have emerged that are worth discussing even today. I will here present five such types, two of which are known to us by common sense and thus without any special legal or philosophical knowledge.

The first type of answer originates from the Old Testament: "You shall treat the stranger who sojourns with you as the native among you" (Moses 3: Leviticus 19:34). According to this principle, the stranger should be treated neither better, nor worse. The continuation of the text states the humanitarian intention of the principle: "you shall love him as yourself." The reason for this kind of equal treatment is connected with the idea of hospitality, which is grounded in one's own experience: "for you were strangers in the land of Egypt." Experience alone, of course, is not yet a justifying reason. Thus, in order to avoid the is-ought fallacy, a further, genuinely moral element is needed. This element, however, can be self-evident in a way that it need not be stated explicitly.

In case of the mentioned verse, the normative element in question can be found in the negative formulation of the Golden Rule: "Do not treat others in ways that you would not like to be treated" (for the Old Testament, cf Tobit 4:15). This rule, a fundamental principle of reciprocity, is universally valid in an empirical as well as in a justificatory way: Empirically, this rule is interculturally valid since it is present in many cultures. It can be found, for example, in Confucius, Thales (as one of the Seven Sages of Greece), in the Indian epic Mahabharata, and in the Old as well as in the New Testament. In a justificatory way, the Golden Rule is interculturally valid since it does not appeal to any presuppositions particular to a single culture. In both regards, therefore, the Golden Rule is part of the moral legacy of mankind.

This kind of humanitarian equal treatment, however, could prove to be inhuman: The stranger, bound to the laws of the host country, loses the right to follow his native custom. Since native custom is quite fundamental to a person's conduct and life-style, it might even result in the stranger rendering himself liable to prosecution. Such cases can vary from minor offenses such as in most countries of Europe, such as fishing without a permit, because such a permit is not required in a person's native country, up to graver offenses – think, for example, of the problem of sexual relationships with minors.

Whoever wants to avoid criminal prosecution needs to adapt to the custom of the host country. This, however, might result in a person estranging herself from her native custom. Here, we thus face a dilemma – the legal dilemma of intercultural encounters: A fundamental principle of justice, equal treatment, might result, if adapted to strangers, in unequal treatment, and thus in injustice: While the natives are allowed to follow their custom, strangers must adapt themselves to new custom, which often is contradictory to their own native custom. This legal dilemma of intercultural encounters thus consists in the conflict of equal treatment and subjection. Mere custom, however, rarely is relevant for criminal law. I leave aside the historical question of whether anybody has ever been legally punished for criminal offenses that were alien to him. The point is that we might find some examples – whether there are many such examples is yet another question.

In the Roman Empire, the dilemma just mentioned is basically known. As a union of states with numerous more or less autonomous states as its members, which were dependent on Rome only in virtue of a law of nations (*ius gentium*), the Roman Empire was in fact a multiethnic state with – in today's terms – a highly complex multicultural society. Within the Roman society, more types of answers to the question of international criminal law emerge, that is, a special law of nations. This Roman *ius gentium* is no law between nations, *a ius inter gentes*, but an international civil law, especially concerning trade. In contrast to Rome's autochthonous civil law, the Quirine *ius civile*, the *ius gentium* is understood to be an intercultural law known to all peoples. Philosophers later grounded this intercultural law on natural reason common to all human beings (*naturalis ratio*). Rome, thus, treated strangers (*hostes*, later: *peregrine*: foreigners) neither according to their own, nor according to Rome's own law. Rather, Rome resorted to a law known to all peoples, so that the dangers did not arise that are present in the passage from the Old Testament – estrangement and subjection.

Roman criminal law, however, is not subsumed under the *ius gentium*. According to Theodor Mommsen, our historical tradition does not link the *ius gentium* to criminal offenses only because the narrow articles of formal civil law are not applied to this realm at all (cf Mommsen, 1899: p. 119). Here, we encounter a third type of answer to our question: The difference between a citizen and a stranger is omitted, since the concept of a crime – public as well as private – does refer to a human being and not to a citizen (cf Mommsen, 1899: p. 118). Thus, we encounter a human right already in Antiquity – albeit in an objective rather than a subjective sense of right: a universal criminal law. In cases of murder, arson, theft, and material damage, it is the person who is morally to blame – regardless if she is a citizen or not.

It should be added that since the offenses just mentioned are counted as universal violations of law, some sort of a criminal law *ius gentium* is in fact drawn upon: An objective condition is employed that is tantamount to the idea of an *ius gentium*: In order to avoid any danger of hegemony, one should employ wide concepts of law, rather than locally or regionally bound concepts. Wherever this condition is not satisfied – think, for example, of the criminal offense of 'heresy' introduced under Christian emperors – there is a case of legal injustice, as well as of political mischief.

Within criminal jurisdiction, a forth type of answer emerges that need not necessarily be understood as an alternative: A further phenomenon is added to the human right of criminal law. This phenomenon reaches into the vicinity of federalism and fulfills the still-existing claim of 'no foreign judges': Especially the Eastern part of the Roman Empire, which was self-confident with regard to its legal culture, retained the right to its own criminal courts for the cities in its jurisdiction.

The civil law-variant of the *ius gentium* is necessary because of a problem that is unknown to modern states that are secular and territorial, but indispensable for a city state in Antiquity: A person became a citizen neither through subordination to a territorial state power, nor through attachment to an ethnic group, but only though active political participation. Since, furthermore, the rights of citizens heavily depended on sacral norms and norms of custom, there was a principle of territoriality rather than a principle of personality: Regardless of her residency, a person lives – a fifth type of answer – according to her law of origin. In this sense, *ius civile* literally means a civil right that is valid for the *cives*, the citizens as members of a *civitas*, a city state, and only for them. It is not equivalent to the meaning of civil law as opposed to public law.

To sum up: The first three types of answers have in common that the stranger cannot simply claim that he comes from a different legal culture. According to the Old Testament-type of law, the stranger is not allowed to appeal to a special status since he is treated equally like any native. According to the Roman civil law, the stranger is not allowed to do so because his criminal offense is to be measured on an intercultural scale. And according to the Roman criminal law the stranger is not allowed to do so since this law applies to humans as humans. While the forth, 'federal' type allows for regional differences, the fifth type – an evaluation according to the laws of a person's home – is important up to this day.

A Case Study

Within the Roman criminal law, the stranger cannot appeal to his being different. But how about issues that are of central importance and, at the same time, quite differently treated within different societies, for example, sexual offenses or matters of honor? As a case study, let me give an example that is close to a real case: A Senegalese man agrees with the parents of a Senegalese girl of minor age to take her with him to Germany and to take care of her within his household. Some time later, he has sexual intercourse with the girl who now is 16 years old.

According to German criminal law, this man is guilty of sexually abusing a child under his charge (cf StGB, § 14). If both the offender and the victim were German natives, the verdict would need to be 'guilty.' However, according to a statement by the girl which the judges considered to be trustworthy, it is part of Senegalese custom that a woman 'offers herself' to the man who takes her into his home as her protector. The girl furthermore stresses that she was not forced to any kind of action; she offered herself to him voluntarily. How is this case to be judged?

Or think of another case: An Arab man marries a second woman while living in Germany. Although this is a custom in his home country, it is forbidden in his host country as 'bigamy' (cf § 171, StGB). To make things more complicated: An Arab man is married in Europe and returns to his native country only for the sake of marrying a second woman, and then comes back to his host country to live there with both wives. Various similar cases can easily be construed. In what follows, however, I will concentrate on the first case study of the Senegal man.

Western or Modern Legal Morality: Human Rights

For a discussion of these cases to be interculturally convincing, the concept of human rights seems to impose itself – provided, however, that this concept is justifiable without recourse to premises particular to a single culture. The various prominent historical conceptions of human beings like the Greek, Jewish, Christian, Islamic, and Buddhist conception of human beings all employ culturally specific elements. Therefore, an argument

that aims at intercultural validity has to depart from these elements in order to function without any ethnocentric elements in both the descriptive and the normative sense. This is not the place to elaborate these two senses in full detail; but let me sketch the direction such an argument might take.

If one turns away from everything that is culturally specific in the descriptive sense for the purpose of an intercultural justification, one is left with the *conditio humana* and its anthropology. Here, one again encounters the danger of claiming universal validity for something that in fact is culturally specific. To overcome this danger, I propose a concept of transcendental interests (cf Höffe, 1999/2007): These are the basic human interests that are the conditions of the possibility of our everyday interests. In this sense, they are logically prior and transcendental. Even if an argumentation along these lines is new, philosophy knows its result since its beginnings. The same holds for other cultures; *de facto* they all recognize these higher-order interests.

Three levels of these culturally indifferent and thus universally valid higher-order interests can be distinguished. To recognize them nothing more than common sense is needed. Whatever interests may prevail in a given society, there exist certain kinds of interests that are the conditions of the possibility of developing interests altogether. These fundamental interests can be described as *conditions of agency*: (1) life and limb, including (material) conditions for living a complete life. Anthropology covers this level by considering the human being as a part of nature, as a living being (*zoon* or *animal*); (2) language and reason: the human being is a *zoon logon echon* viz. an *animal rationale*; and last but not least; (3) a general sociability: the human being is a social animal (*animal sociale*); and (4) a more particular capacity for being political: the human being as the *zoon politikon*, including the concepts of law (*animal juridicum*) and political society (*animal politicum*).

There maybe objections to every level. They can, however, be countered. Against the thesis of a logically prior importance of life and limb one might, for example, refer to martyrs and suicides, which in different ways relativize the interest for life. But since even these people want to decide what for, when, and how they are going to die – otherwise they would simply be killed – life and limb remain conditions for agency even for them. For securing all of these three descriptive levels, law and a morality of law are needed.

If one abstracts from everything that is culturally relative on the other, normative, side as well, one is left with the following: an idea of a regulation that rejects any despotism and violence that realizes this objection universally and thereby allows for an advantage for everyone concerned. Such a regulation can be labeled 'legal-practical reason.' It can be realized in three steps of increasing recognition. On the first step – realizing law – certain rules are introduced. On the second step – legitimizing law – these rules are strictly enforced. And on the third step – standardizing law – the rules are subjected to second-order moral rights.

So what about justification? With regard to the first level of transcendental interests – the human being as a living being with a body – the argument goes like this: Concerning his biological make-up, the human being is a possible victim as well as a possible perpetrator of violence. This fundamental situation of human beings, their *conditio humana socialis*, is answered by the morality of law: According to the concept of human rights, every human being has a subjective claim not to fall victim to violence. To put this positively: a right to life and limb.

In order to justify this right, the presupposition of an interest, even a fundamental transcendental interest, is not sufficient: From an existing interest, we can infer no claim to recognition of this interest by others. A further argument is needed. This argument starts from the observation that subjective rights are only present where others take on certain obligations; human rights are bound to respective human obligations. For example, the right to life and limb of a given person is tantamount to the obligation of all other persons to refrain from violence.

Now generally a claim to a benefit exists where this benefit is offered under the caveat that a certain similar benefit is to be expected. Claims justify themselves from reciprocity, pars pro toto: from an exchange. In order to justify human rights as subjective rights, one needs to establish a reciprocity that is part of the human being simply in virtue of being human. This situation exists when an interest of reciprocity, which is indispensable to human beings, can only be realized in reciprocity and through reciprocity. At this point, where interests are indispensable and, at the same time, bound to reciprocity, indispensability is transferred to reciprocity; the respective exchange is itself indispensable. It is not that a human right exists simply because every human being has a (higher-order) interest in life and limb. It exists, first, because this interest can only be realized in reciprocity and, second, because in the resulting 'system of reciprocity,' everybody already makes use of the benefit – the renunciation of violence by others – which is provided only by the reciprocal benefit: one's own renunciation of violence.

Principles Open for Different Cultures

The result so far is thus: Human rights are not specifically a European or Western phenomena; rather, in human rights, something common to all human beings breaks through. "Breaking through" entails a moment of evolution. Insofar as the West breaks through and other cultures do not, these other cultures might appear to be less developed. The notion of being less developed has an arrogant ring to it, which is why these cultures in question try to defend themselves against such a description. An intercultural legal discourse at this point demands caution.

In the encounter of the West with other cultures, nowadays for instance with China and Japan, a reciprocal give and take occurs. And insofar as the West demands respect for human rights from these other cultures, the West has to ask itself from time to time, if it is really human rights, simple and pure, that are being demanded, or if it is not rather a mixture, a combination of human rights with Western peculiarities, special experiences, maybe even special interests. For this reason, a *hypothesis of contamination* is sensible: The hypothesis that the alleged human rights are in fact contaminated with other elements.

Although every alleged human right can be infused with nonuniversal elements, this hypothesis does not demand total restraint. It simply demands the effort of a careful

interpretation. From the hypothesis of conglomeration, the duty of decontaminating arises. Just like the analytical chemist one needs to separate the particular from the universal in order to arrive at the real and original human rights. It is only with this effort that philosophers fulfill their duty that they have adopted ever since Greek Antiquity – the duty to ground everything solely on human reason common to all. If the philosophers fulfill this duty, they may call themselves, even if they are only modern European, with Husserl (1936/1970, 17) 'functionaries' or, even better, 'lawyers' of humanity.

It is not only the lawmaker who needs to remain culturally open when formulating human rights and criminal law in accordance with them. The judge, too, needs to remain culturally open in order to be able to judge reasonable in cases of criminal law that arise from typical conflicts of cultures.

Case Study: Further Inquiries

Let us return from these fundamental considerations back to our first case study – the Senegalese man – and let us try to weight the interests of the perpetrator and the victim. The considerations concerning their respective interests lead to certain further inquiries.

1. Perhaps the victim and the perpetrator have been in Germany only for a short time? In this case, one could consider them as people who are passing through, and whose business we need not meddle with. But let us suppose that in our case they have been in Germany for quite some time. Since this time could extend into years and maybe even decades, a political question arises: What is better for a young Senegalese woman, the – allegedly – sparse security of law in her home country, or the more encompassing security of law of the society in which she has been living for quite some time, and will possibly continue to live in even throughout her whole life?
2. Did the girl perhaps count as an adult at the age of 16 in her home country? If so, the judges might consider a mistake as to the wrongful nature of the act: One could assume that the offender had sexual intercourse with the girl only because he believed her to be an adult. Since questions about the legal age, however, are fundamental, one cannot simply assume such a mistake on behalf of the perpetrator, since he has been living in his host country for quite some time – one would at least need to consider this mistake as having been avoidable.
3. What exactly was the nature of the agreement between the man and the parents? Maybe there has already been some sort of compensation given to the perpetrator by the parents, in which case the perpetrator could be considered as having taking a double compensation.
4. If one remains at the level of custom, one could ask how voluntarily the girl's agreement in fact was. Furthermore, mere voluntariness does not in itself lead to the action not being a criminal offense. In effect, one could argue that it is hard to assume voluntariness, since the action took place within a framework of possibilities sketched by custom, which leaves but a few ways to act: Every custom and tradition limits possible ways of action. In the case at hand, this limitation goes further than in other cases: The sexual devotion in this case is a donation in return for another donation. Here, the principle of justice of exchange is called for. Taken care of by the perpetrator, the victim assumes that she owes sexual obedience to him in return. The alleged voluntariness, thus, occurs within a frame of nonvoluntariness, the feeling of owing something to somebody.
5. What is the status of the custom in question from the perspective of criminal law? The Senegalese system of law is oriented along the French system of law, and thus along a European legal tradition, so that an argument for a right for exemption from German criminal law cannot be made on solid ground – as it would be the case with a totally different legal culture. Within the new French *Code pénal*, the article in question would be 227, 27: Abuse of a person under one's charge in a case where the victim is older that 15 years, but still a minor and not emancipated though marriage. Within the old *Code pénal*, which is valid for Senegal, it is article 331-1, which in turn essentially corresponds to §174, of the German criminal law (StGB).
6. The content of the custom in question is related to a traditional, and also patriarchal society, in which – in the case of Senegal – 90% are Muslims. Since it is known what kind of value virginity has in these societies, the custom in question results in a very grave disadvantage for the girl. This situation should make us hesitant when facing the claim that this is simply a foreign custom that needs to be respected. If we take the high value into account that virginity has in these societies, an argument for a right for exemption in this case, again, can hardly be made on solid ground.
7. One could ask if the essential part of the offense – 'abuse' – could be dropped, because the relationship in question in fact is a relationship of mutual love. Against that, however, stands the recourse to a Senegalean custom, and thus to a tradition rather than to love.

An Intercultural Criminal Law

These kinds of further inquiries show that encounters between different cultures do not simply lead to situations in which the strangers can refer to their different legal cultures. Furthermore, there are experts who argue that some Africans, Indians, and others tend to use double standards with regard to Western cultures: In cases where the host culture demands a higher form of responsibility, they refer to their native legal culture, and when in their home country, they refer to Western legal culture.

In order to keep things simple, let us assume that all further inquires that we mentioned are being answered in favor of the perpetrator. Then, the key question remains: How far does the coercive power of a legal culture extend in such cases?

If we would simply need to overcome the allegedly culturally biased sentences, the case would be easy: Modern societies overcome fragments of cultural narrow-mindedness. In this sense, they have cleared their criminal law of such traces over time and deleted offenses like suicide, homosexuality, heresy, lese majesty, and criticism of the state. For the most part with criminal offenses, especially

with regard to those concerned with life and limb, there exists no cultural bias. On the contrary, these are the laws that preserve human dignity as spelled out through the human rights that are known almost universally; there is no known legal culture that does not include killing as a criminal offense.

Now, to return to our case, does sexual protection of minors fall under the charge of being culturally biased? At least prima facie, the contrary is true: Through this kind of protection, cultural biases are overcome, for example, the tendency of patriarchal societies not to consider women and children as equal.

Therefore, the question can now be answered: Insofar as the criminal offenses can be justified with reference to arguments of human rights – and this is the case with the majority of offenses, especially in liberal legal cultures – an intercultural criminal law in fact exists. The reason for it does not consist in the arrogance of a legal culture to subject strangers. It does also not consist in the idea of refusing the stranger a right of being exempted from criminal law. Finally, it does not consist in the (certainly justified) interest of a society for its own protection. The reason in question, rather, is the fact that from the perspective of criminal law the remote stranger does not exist: It is hard to come up with legal cultures that are so radically different that they do not know offenses the prohibition of which is justifiable through human rights. And even if such cultures would exist, one could demand that its members recognize human rights as soon as they travel to another society, since the offenses are justifiable through human rights. Intercultural law, therefore, reinforces the basic idea of intercultural legal discourses: Whatever we consider to be fundamentally important, we discover in different cultures, as well. And whatever we regard as fundamentally blameworthy, others do so, too.

Interest Groups

Abstract

Interest groups – for example, business and professional associations, labor unions, and environmental and consumer groups – are a feature of every functioning democracy. All interest groups perform certain functions: providing information to public officials; seeking to persuade policy makers to pursue a preferred course of action, an activity that may be difficult to distinguish in practice from the attempt to inform; and communicating with and educating members. Within the context of these widely shared functions, organized interests vary substantially both within and across democracies with respect to the difficulty they face in gaining access, the techniques they use to influence policy, and the targets of their activities. In addition, political systems differ in terms of the structure of relations between interest groups and government: some political scientists have suggested that there are two basic patterns of organized interest interaction with the state, neocorporatist and pluralist. In terms of the kind of citizen interests represented by groups, although there are both substantial differences across democracies, the interests of producers are inevitably well represented. Two recent developments affect interest-group politics on a cross-national basis: the emergence of interest representation at the European Union and the emergence of greater pluralism in democracies everywhere.

Among the requisites for democracy on a sustained basis are not only free and fair elections but also the rule of law, respect for dissent and freedom of expression, and the legitimation of the organized representation of citizen interests – often in opposition to those currently in power – through parties and interest groups. Interest groups, those myriad organizations – ranging from business and professional associations to labor unions to environmental and consumer groups to groups concerned about issues as diverse as abortion and nuclear power – that link the individual to public institutions and seek to influence public policy, are a feature of every functioning democracy. Although they may be present in nondemocratic systems as well, it is not an exaggeration to claim that democracy on a national scale is impossible without interest groups.

Problems of Definition

Differences of opinion arise in any discussion of how to categorize the various collectivities that mediate between the individual and the state in a democracy. Many of the institutions often described as interest groups – for example, corporations, foundations, or public bodies such as regional governments – are not groups at all, in that they do not have members in the ordinary sense. For this reason, some analysts prefer the term 'organized interests' to 'interest groups.' Interest groups have much in common with other social aggregates that represent citizen preferences to policy makers in a democracy. In fact, organized interests often have connections, formal or informal, with political parties or social movements. However, unlike political parties, they do not nominate candidates to campaign under their name for the purpose of running the government. They contrast with social movements in their greater degree of formal organization.

Interest Groups and the Policy Process

Wherever they are, interest groups serve as intermediaries in a two-way process of communication linking a citizen constituency with policy makers. All interest groups perform certain functions: they provide information to public officials to assist in designing policy; they seek to persuade policy makers to pursue a preferred course of action, an activity that may be difficult to distinguish in practice from the attempt to inform; and they communicate with members – keeping them apprised as to what the government is doing, educating them about the political process, and cultivating support.

Within the context of these widely shared functions, organized interests vary substantially – in ways that reflect the degree of permeability of the political system to new interests, and the nature and relative importance of formal political institutions – with respect to the difficulty they face in gaining access, the techniques they use to influence policy, and the targets of their activities. Newly emergent groups have much more difficulty penetrating interest group politics in Israel, which has a strong, centralized state, than in the USA, with its tradition of voluntarism and a public domain that, because it is divided by federalism and separation of powers, provides many points of access. Within and across polities, there is tremendous variety in the kinds of techniques groups use to realize their objectives. France, for example, has a tradition of direct action by groups not present in, say, the UK. Within any single country, organized interests differ in the extent to which they function solely as insiders utilizing traditional, low-profile means of achieving political influence or operate as outsiders, adopting more public tactics of mobilization and protest – with unions and environmental groups more likely to engage in protest activities than, say, business associations.

In choosing where to direct their energies, organized interests inevitably gravitate to power. Hence, the primary focus of interest group activity in Japan is the bureaucracy, while in Italy it is parliament. In a system as fragmented as the US political system, interest groups often have choices, and may seek to locate a political controversy in the institutional arena in which they would have the greatest probability of success.

Political systems differ not only in terms of what interest groups do and where they channel their activities but also in terms of the structure of relations between interest groups and government. Some political scientists have suggested that there are two basic patterns of organized interest interaction with the state: neocorporatist and pluralist. According to the neocorporatist model, approximated most closely in Sweden and Austria, mechanisms providing for equal representation of individuals on a geographical basis are supplemented by mechanisms providing for functional representation of organized interests – ordinarily by a relatively limited number of peak associations. Such organizations are recognized and licensed by the state and attain a regularized role in policy making through delegations of administrative power or participation on public councils or committees. Important government decisions are made only after consultation with major economic interests, most notably workers, employers, and farmers.

In contrast, according to the pluralist model, interest groups are much more numerous – less highly aggregated and organized around multiple bases of political conflict – and much more autonomous. Pluralist interest-group politics, approximated most closely by the USA, is relatively permeable to the entry of new groups, and groups arise and get involved in politics at their own initiative, rather than at the behest of the state. In a politics of pluralism, interest groups have greater freedom in choosing which political battles to fight in which political arenas. Typically, those battles involve shifting, issue-specific coalitions taking sides on issues of narrower, more limited import.

It is essential to recognize that these alternative models, which have generated considerable scholarly discussion and some controversy, are ideal types. No polity actually conforms to either model, and many countries – for example, France where a strong, centralized state has meant comparative weakness for interest groups, or Japan where regular consultation between business and government more or less excludes labor – evidence a pattern that is neither pluralist nor corporatist. Furthermore, in most countries no single pattern obtains for the making of policy in all issue areas: the formulation of foreign policy, for example, is less likely to entail regularized bargaining with interest groups than the making of agricultural policy.

Interest Group Systems: Who is Represented?

Reflecting national differences in their political traditions and political culture, in the number and depth of politically relevant social cleavages, and in the number, strength, and ideological distinctiveness of the parties, there are also, across democracies, enormous differences in the nature of interest systems, the collective set of organized interests active in politics. Polities vary widely in both the number of groups and the proportion of citizens who are members of any group at all; in the Scandinavian countries, where most employees belong to some kind of union or professional association, membership is much higher than in, for example, Italy or Greece. There are also differences in the nature and number of the axes of political cleavage encompassed in organized interest politics; the multiplicity of kinds of interests represented in the interest groups of a large and diverse country such as the USA contrasts with that in a relatively homogeneous country such as Norway.

In addition, interest group systems vary substantially in the degree to which interest representation is highly aggregated or fragmented functionally or geographically and in the extent to which interest groups have a monopoly on the organization of a particular constituency. For example, in contrast to the centralized interest group systems of Austria and Sweden are those of the Netherlands, where business associations are organized according to religious differences, or Belgium, where business associations are divided along regional lines but labor is pillarized into socialist, liberal, and Catholic national federations. Furthermore, there are marked differences in terms of the relative strength of organizations representing different kinds of interests – in particular, in the vigor of the opposition provided to traditionally powerful business organizations by organized labor and citizens' groups concerned about consumer and environmental issues.

There are, however, certain regularities in the kinds of interests represented by interest groups. It is difficult to think of a democracy with active interest group politics where producer interests are not well represented – whether by peak employer groups, sectorally based trade associations, or corporations acting individually. In contrast, with the exception of pensioners, the interests of those who benefit directly from welfare-state policies – for example, students or recipients of public assistance – rarely receive vigorous advocacy by interest groups although their causes may be championed by political parties.

Interest Groups and Parties

That the political parties in a democracy might represent interests not being championed by organized interests – and vice versa – makes clear that an overall assessment of the way in which citizen interests are represented in any particular democracy requires that its interest groups be considered in the context of its parties. Common wisdom holds that strong parties go hand in hand with weak organized interests and, conversely, weak parties with strong organized interests. In the USA, a plurality of groups broadens substantially the range of interests represented in politics by two relatively weak and ideologically moderate parties. However, strong parties do not necessarily preclude strong interest groups. Sweden has strong political parties, and interest groups are guaranteed a consultative role in corporatist policy making in the system of state commissions. And France has traditionally been characterized as having both weak parties and weak interest groups in the face of a strong state.

Democracies also differ in the extent to which interest groups have strong links to like-minded political parties. For example, at least until recently, UK trade unions have had a much closer relationship to the Labour Party than their US counterparts do to the Democrats.

The Evolution of Interest Group Politics

In spite of the substantial differences across democracies, there have been, over the past few decades, two related developments

affecting interest group politics on a cross-national basis that suggest the possibility of convergence among democracies. First is the emergence of interest representation at the European Union (EU). Although group activity in Brussels often arises within individual EU nations, many of the groups involved are either individual corporations or European-level, rather than national, organizations.

The second important trend is an advocacy explosion in democracies everywhere with – in a fragmented, pluralist fashion – more concerns being represented by more groups, and a greater reliance on professional lobbyists. This fluid style of interest advocacy is especially characteristic of the EU but has appeared in the national capitals as well. With respect to the kinds of interests represented, a growing number of citizens' groups concerned about an array of issues including nuclear proliferation, the environment, immigration, and the rights of gays, women, and ethnic minorities supplement traditional economic groups representing business, farmers, and workers. How these developments will alter interest group politics is not yet clear. Nonetheless, private associational life will surely remain essential to the functioning of democracies around the world.

Abstract

Modern interest groups can be defined as voluntary associations of individuals, firms, or smaller groups uniting in order to defend or fight for a common interest, with the intention to influence and intervene in the political process, but without ambition to form a political party. Basically, eight types can be distinguished. Their shape, functions, patterns of organization, and modes of interaction depend on the specific constellations and trajectories of a given polity, and so does their democratic potential. The systems of interest intermediation (between pluralism and corporatism) show different degrees of institutionalization. Major transformations at the end of the twentieth century have given rise to tendencies toward more fluidity and transnationalization.

Organized interests and groups, their factions or parties fighting for influence and power in a given polity or beyond, go back a long way in history. In modern political theory, the notion of 'interests' was first narrowed down by enlightened philosophers from Machiavelli to Montesquieu to material and rational interests, as opposed to and counteracting the 'passions' (Hirschman, 1977). James Madison and the Federalists considered both the passions and the different material interests, particularly of 'those who hold, and those who are without property,' to be the principal sources of factions in a society that could only be contained and controlled by building adequate institutions with a sufficient number of checks and balances (Hamilton et al., 1961; 'Federalist 10'). The concept of interest groups, although under different labels, and of interest politics in a more specific sense, began to proliferate in the Western world from the beginning of the nineteenth century when, after the American and French revolutions, the world of political parties and factions started to dissociate from the universe of interests at large and when the unequal progress of industrialization in different parts of Europe induced individuals, firms, and groups to articulate their interests in determined policies in order to improve the economic or institutional prerequisites, or cope with the social consequences of industrialization.

Therefore, the modern interest group might be defined as a voluntary association of individuals, firms, or smaller groups uniting in order to defend or fight for a common interest, with the intention of influencing and intervening in the political process, but without ambition to form a political party (exceptions notwithstanding). A number of similar terms correspond to the same definition: pressure groups, organized interests, lobbies, power groups, advocacy groups, the German 'Verbände,' the French 'syndicats,' American 'chambers,' and many 'institutes' or 'associations.' (Functional equivalents in the non-Western world are excluded here.) The more general term 'associations' also indicates proximity to and overlaps with the broader spectrum of civil society organizations (CSOs), which may also be labeled as nongovernmental organizations (NGO), voluntary-sector or nonprofit organizations (NPO), social movements, or otherwise (Della Porta et al., 1999; Maloney and Roßteutscher, 2007). All these groups usually also display functions and aspects of interest groups, so that the issue of commensurability of 'interest group aliases' has recently been raised in the literature (Halpin, 2010). As the interest groups' activities are usually directed toward the political arena asking for specific legislation, allocation of benefits and state intervention promoting their interests, the rise of state interventionism and of the modern social and welfare state since the last quarter of the nineteenth century has been closely intertwined with a secular proliferation of interest groups of different types. On the one hand, these usually reflected the characteristics of the (more or less democratic) political systems in which they originated. On the other hand, the groups' activities have often significantly contributed to modifying and modernizing the political systems and to establishing new rules and patterns of interaction. Their recognition and legitimation not only have been products of their performance but also have been dependent on the general theoretical and ideological orientations of the political consensus within a given polity, which could vary from authoritarian or Rousseauist views of single or 'particular' interests as being categorically detrimental to the common good to more pluralistic Anglo-Saxon approaches of accepting different interest articulations as expressions of a vital civil society (Tocqueville) and of taking factions for granted as vehicles of political agency (Fraenkel, 1964). In order to overcome some of the implied shortcomings of legitimation, interest groups have usually tended to develop ideological mechanisms of their own to demonstrate that their particular interests serve the common good or coincide with the interests of the community. For the great majority of interest groups, through the nineteenth and twentieth centuries, the common and still most important frame of reference has been the traditional nation state, whereas it appears that, since the 1990s, a significant process of transnationalization and 'Entgrenzung' of economic, societal, and political constellations has gained momentum, which may constitute a secular threshold in the development of the structures of politics and of the public sphere, and affect and (partly) reshape not only firms, corporations, the media, social movements, and political organizations but also interest groups. The most relevant forces behind this process are the breakthrough of the 'network society,' with all its technological and economic consequences, advancing globalization (and fragmentation) and the repercussions of regional integration (such as the European Union) and the great economic crisis.

Types

Interest groups have developed into different types. They could organize individuals, firms, associations, or public corporations (cities, states, provinces, and legislatures) at a local, translocal, national, or transnational level and develop different characteristics. With regard to the contents and quality of the interests involved it could be said that, with some simplification and not accounting for the various mixes and marginal or exceptional cases, most of the groups of the 'classical' spectrum of the nineteenth and twentieth centuries may belong to one of the following eight types: (1) professional associations; (2) business, commercial, or industrial groups; (3) labor unions; (4) agricultural organizations; (5) single (nonprofessional, nonproducer, nonpublic) interest groups; (6) ideological interest groups; (7) public interest groups; and (8) welfare associations. With regard to the more recent trends of restructuring and re-forming the public sphere, it will also make a difference (1) whether the groups are national (regional) or transnational interest groups, (2) whether they move within the consensus of what might be called an (informal) 'capitalist international' or have become 'antiglobalist,' and (3) whether they are loosely coupled ad hoc organizations (and movements) or develop structures.

(1) The most 'classical' case seems to be that of the professional associations that have taken over many of the functions of the premodern guilds, estates, brotherhoods, or clubs, particularly in regulating the requirements and mechanisms of co-optation and access to a number of key professions, be it as a privilege of professional self-government as in the United States (American Bar Association and American Medical Association) or as a task delegated by the state as in most of the German 'Kammern' (of lawyers, doctors, and artisans). The various medical associations have become particularly differentiated with the rise of compulsory health insurance or comprehensive national health services (cf. the German Kassenärztliche Vereinigungen). The organization of less professionalized groups such as teachers or employees in trade and commerce has often followed the lines of professional associations, if they did not unionize in the labor ranks as in most Latin countries.

(2), (3) The two predominant camps of interest groups of the industrial era, the associations of industry and the labor unions, have typologically developed out of earlier commercial guilds or professional associations of craftspeople and workers. The labor unions in industry have usually been able to acquire more strength and influence since they began to overcome their traditional fragmentation along the lines of professions and crafts, and started to form broader industrial unions – in Germany since the 1890s, in the United Kingdom after World War II, and in most other industrial countries during the 1920s and 1930s. In industry and labor, it also made a great difference whether there evolved a coordinating peak association or confederation, or whether there were two, as in German industry before 1919 or in Spanish labor before 1939 and after 1975, or a more fragmented variety, as in the United States. In case labor relations became institutionalized, the industrial sector and its associations occasionally created separate employers' associations with the specific objective of coordinating negotiations with the unions. Banking, insurance, and small business interests in most countries have also organized separately.

(4) Most agricultural interest groups, which came into existence from the last third of the nineteenth century, besides voicing the interests of 'agriculture' against industry and the industrial world, have reflected the structures and divisions of the various crop sectors or regions in their nation's agricultural economies, with the interests of larger producers usually dominating those of the smaller ones, a high influence of specialized production interests notwithstanding. In less developed countries or regions with a greater number of dependent small peasants and landless laborers, agricultural interests have also been organized into labor unions and social movements. In some countries (such as France) and in determined historical periods and constellations in others (such as Italy, Spain, and the United States during the Populist Era and Germany and the United States during the Great Depression) the mode of agricultural interest articulation could oscillate between interest group politics and social protest.

Two other 'classical' types are constituted by groups dedicated to voicing (5) a single nonprofessional, nonproducer, and nonpublic interest – for example, the National Rifle Association in the United States, automobile associations, groups advocating or fighting particular forms of exclusive or commercialized sports or entertainment, or the various (often 'ethnic') associations of migrants, refugees, or victims of wars and (6) by more ideologically inspired groups like those advocating imperialism, temperance, or prohibition (Anti-Saloon League), or fighting abortion or the death penalty. A number of single interest groups claim to be contributing to the public good by improving people's health – for example, most large sports associations – or by promoting human progress and empowerment of the underprivileged – for example, many organizations of minorities and of women in the United States (such as the National Association for the Advancement of Colored People, the Leadership Conference on Civil Rights, and the National Organization for Women) and in other countries. Here we also have to count a more recent type of mobilized group that has been triggered by the advancement of globalization and economic crisis since the last decade of the twentieth century and often overlaps with (increasingly transnational) social movements: the broad variety of 'antiglobalist,' and in a new way antiimperialist (and mostly anticapitalist) organizations, such as 'attac' or 'occupy.'

(7) Some of these groups might also be considered to belong, at least partly, to the type of public interest groups, the most common issues of which in the United States – following more than a century of honorable precursors such as the Anti-Slavery Society (1833) and the American Civil Liberties Union (1920) – since the 1970s have been environmental and consumer interests (Common Cause, Public Citizen, Consumer Federation of America; McFarland, 1984). In Germany and some other Central and West European countries, antinuclear and pacifist issues would have to be added. At the transnational level, groups like Greenpeace, Amnesty International, or Transparency International would belong to this category, not to forget a number of 'classical' precursors, such as the International Committee of the Red Cross (Keck and Sikking, 1998).

(8) The heterogeneous groups that might be labeled as welfare associations often combine professional interests, particularly of social workers, with those of public entities, mostly cities and counties, and the single and ideological interests of churches, religious communities, and other private agents in the welfare arena, which in parts might also be considered as serving the public interest. Many organized themselves early on into coordinating central or national associations or corporations, such as the National Conference of Charities and Correction (1874/84) in the United States (professional interests prevailing) or the Deutsche Verein für Armenpflege und Wohltätigkeit (1881) in Germany (corporate interests prevailing), long before sectoral peak associations were formed.

The various forms of intergovernmental lobbying will not be considered here because they are about influence and allocation of benefits within the public sphere only. Hence, neither the National Governors' Association and the US Conference of Mayors nor the German Kultusministerkonferenz and the Deutsche Städtetag will be considered as interest groups. The same applies to the often well-organized lobbies of foreign governments in Washington, DC, or to the representation of state or regional interests vis-à-vis the European Commission in Brussels even if they seek to increase their influence by behaving like private interests. Likewise, the numerous Political Action Committees of American interest groups, which have basically been founded for legal reasons with the specific purpose of influencing legislation, might not be considered as being a separate type of interest group, because the interests voiced by them are the same as those of their creators (Cigler and Loomis, 2012).

Alternative typologies might differentiate between status quo defenders and agents of change, or according to the constellations of the groups' organizational density and power: whether they rely more on money or on numbers, on machines and bureaucrats, or on mobilization and agitation; whether they wish to influence legislators en petit comité or think they need a broad public forum (which also depends on the political system); or whether or not they need a high level of identification or have to provide a variety of services in order to secure their members' loyalty (such as automobile associations). Among the most basic and influential differences are those between big and small interest groups and between big and small constituencies. Smaller constituencies (such as steel or farming interests) are usually much better organized and represented than broader constituencies (such as consumers), which tend to fall victim to the mechanisms of the 'free rider' effect (Downs, 1957; Olson, 1965).

Constellations and Trajectories

The shapes of interest groups and of the evolving national systems of interest intermediation have been significantly influenced by the particular economic, social, and political constellations; institutional sets; and the distinct paths and trajectories of modernization of the different countries and societies. Of particular importance here are the peculiar relations and mixes of the developments in the three most important dimensions of the modernization processes, which, simplified, might be labeled as bureaucratization, industrialization, and democratization. In the United Kingdom, industrialization has triggered democratization, and bureaucratization came late, basically in order to cope with the social consequences of industrialization. In the United States, which followed a similar pattern, the elements of democratization were stronger from the beginning, although moderated by federalism, and more checks and balances. On the European continent, bureaucratization has been the legacy of early state building under absolutism, but here the French revolution has made the great difference. In France, the bureaucratic factors combined with the different lines of democratization (representation by notables or Bonapartism, with its peculiar 'deliberative' mechanisms), whereas in most of the German states, democratization was postponed, and the characteristic patterns of modernization were dominated, down to the mid-twentieth century, by factors combined from the sets of bureaucratization and industrialization.

These different constellations have influenced the emergence and performance of interest groups with regard to their social bases and opportunity structures; their strategies and addressees, organization, modes of operation, and achievements; and their relationship with governments, parliaments, and political parties. It is important to note that of the United States and Germany – two countries that have shaped the Gestalt of modern interest groups for the twentieth century more than any others since the breakthrough of organized mass politics between 1890 and 1910 – one was not democratic. In Germany, the government was not accountable to parliament, and the decades of Bismarckian authoritarianism had weakened the political parties and given the (supposedly less political) interest groups better conditions to flourish than anywhere else.

Different Patterns of Organization

In Germany, as in many other European countries, the interest groups developed typologically in three waves:

1. Most of the associations of the first wave, some of which dated back to the first decades of the nineteenth century, were by 1900 closely cooperating with the state bureaucracy, and had become part of privileged semiautonomous corporations or 'chambers,' of agriculture, commerce, and the trades, which could no longer oppose government policies.
2. The second wave was initiated by the protectionist groups of heavy industry (Centralverband Deutscher Industrieller, 1876) and, although to a lesser degree, by heavy agriculture, in response to the great deflation of the 1870s whose principal addressees were bureaucrats and legislators. The same characteristics of interest representation vis-à-vis parliament and the executive, but not much mobilization, can be found in most groups of business and industry that were emerging during the same period in the industrial countries – usually divided into protectionists and free traders. In the United States from the 1880s, a two-tiered system was emerging with national associations like the National Association of Manufacturers (1885) and the US

Chamber of Commerce, and thousands of influential trade associations representing the various branches of production. In US agriculture, however, populist protest preceded organized lobbying (see below).

3. The groups of the third wave in Germany went beyond the previously established patterns of interest representation in that they started massive and permanent propaganda campaigns and began to influence elections, political parties, and individual politicians. They entered the stage at a time, from the 1890s onward, when the progress of industrialization induced by new technologies combined with the extension of the public sphere and the political mass market, modernization of party organization and the proliferation of social Darwinism, and imperialistic rhetoric to create an ambiente favoring a new type of vigorous, aggressive, and well-organized interest group working the public. Among these groups were the protectionist and interventionist Farmers' League (Bund der Landwirte, 1893), various petty bourgeois groups of the 'old Mittelstand' (artisans and shopkeepers), and a number of imperialistic propaganda associations like the Pan German and the Navy League. These groups were at the core of the politics of the New Right against liberalism and social democracy. They contributed much to the modernization and radicalization of conservative groups that now turned ultranationalistic and racist, and to the irreconcilable right/left polarization of the social and political forces active at the end of the monarchy that was to continue during the Republic of Weimar, which it helped to undermine (Puhle, 1975; Ullmann, 1988).

One of the models the German interest groups of the third wave decided to follow was that of 'social democracy,' meaning the party and the labor unions that soon after their emergence from clandestinity under Bismarck's Anti-Socialist Law in 1890 created efficient bureaucratic machines and initiated wide-ranging activities in expanding and consolidating the movement – which went far beyond the scope of what the earlier traditional crafts unions and associations of mutual assistance had achieved since the 1850s. The 'General Commission' of the social democratic unions, from the late 1890s, came close to what might be called a peak association of labor, despite the existence of some smaller catholic and liberal unions. The powerful industrial unions, particularly those of the metal workers and miners, could claim to be the most modern in the world. Their position was further enhanced by the fact that industry and the new employers' associations, from around 1900, began to negotiate with them on a regular basis, usually at the regional level. Besides bureaucratic traditions, the modern unions contributed to an early emergence of institutionalized labor relations in Germany, and vice versa.

In the Unites States, both the organization of industrial unions, most visible in the Congress of Industrial Organization (CIO), and institutionalized labor relations, although much more fragmented than in Germany, were not achieved before the New Deal reforms of the mid-1930s (Bok and Dunlop, 1970; Schönhoven, 1987). Most of the unions within and outside the American Federation of Labor (AFL, 1886) were organized for much longer along the lines of the traditional crafts, although not as long as the UK unions of the Trades Union Congress, which nevertheless managed to dominate the Labor Party for the first two-thirds of the twentieth century. The AFL and the CIO were reunited in 1955. In France, Southern Europe, and other parts of the world there has often been more competition between unions of different ideological and political 'colors,' which have close ties to their respective parties.

Many European interest groups of the third wave, particularly in agriculture, also saw a model in the American Populists. It is interesting to see, however, that the sequences of different modes of organization and political performance of the agricultural interests in Germany and the United States have somehow been inverse. In Germany before 1933, the prevailing patterns went from ordinary lobbying to protest and mobilization; in the United States it has been the other way, some limited revivals of protest in the Great Depression notwithstanding. The Populist revolts were followed by extensive and efficient lobbying techniques as established by the American Farm Bureau Federation (1919), now also taken up by the older National Grange (1867) and National Farmers' Union (1902). In the United Kingdom and Scandinavia, traditional sectoral lobbying has prevailed throughout. In France, one could always find several different modes of operation simultaneously – lobbying in the channels of notable politics by the big producers, mostly in the north, which organized themselves in catholic and radical groups, and protest and mobilization on the part of the smaller producers, notably the winegrowers, mostly in the south. Interest representation has hence been more fragmented, and a second tier of special product interests (associations spécialisées) has been influential. Since the 1950s, the coordinating function of the Fédération Nationale des Syndicats d'Exploitants Agricoles has become stronger. Small peasants and laborers in the French South were eventually organized in socialist unions, and in parts of Italy and Spain also in anarchist and anarchosyndicalist unions (Hervieu and Lagrave, 1992).

Systems of Interest Intermediation

The most common modes of interaction of the interest groups are still those taking place within the traditional nation states. The various interest groups interact with one another and with the legislative and executive branches of the governments, in national (occasionally also regional) systems of interest intermediation, the organization of which follows distinct patterns. These patterns depend, among other things, on the respective intensities and traditions of democratic and parliamentary government, and state interventionism. They usually oscillate between the two poles of more liberal and market-oriented pluralism, and more regulated and institutionalized corporatism, be it in the authoritarian 'state-corporatist' tradition (mostly of fascist extraction) or in the democratic variant of 'societal corporatism' or 'neocorporatism.'

Modern corporatism was originally defined by Schmitter as "a system of interest representation in which the constituent units are organized into a limited number of singular, compulsory, noncompetitive, hierarchically ordered, and functionally differentiated categories, recognized or licensed (if not created) by the state and granted a deliberate representational

monopoly within their respective categories in exchange for observing certain controls on their selection of leaders and articulation of demands and supports" (Schmitter and Lehmbruch, 1979, p. 13).

Among the essential prerequisites for the emergence of corporatist mechanisms or systems are usually counted the existence of peak associations, strong reformist labor movements, a propensity for state interventionism, and a readiness for interparty cooperation, if not consociationalism, in the political arena (Lijphart, 1984; Puhle, 1984). In reality, however, this 'pure type' of corporatism has been as rare as its opposite, the nineteenth-century model of liberal pluralism.

The systems of interest intermediation of most developed countries seem to have evolved into one of the two most frequent 'mixed' patterns. One is an organized and more or less regulated pluralism, often with strong oligarchic tendencies, which usually began with 'regulation by the regulated,' as in the United States during the Progressive Era. The other is a syndrome displaying corporatist mechanisms in a number of important sectors, not, however, adding up to a full-fledged corporatist system except in very few countries, such as Sweden, Austria, or the Netherlands in their 'classical' postwar periods. Occasionally, the two patterns even seem to converge: the 'iron triangles,' observed in certain sectors until the late 1990s, of a pluralist pattern of interest intermediation such as the American, came close to the classical 'tripartite' arrangements between industry, labor (both ideally represented by peak associations), and the state in corporatist systems (Streeck, 1994).

The degree of institutionalization of the mechanisms of interest intermediation could also vary on a sliding scale of at least four different intensities. These range from almost none (lobbying in the open political market) to codified advisory or deliberative functions of interest representation – either ad hoc, as in parliamentary hearings, or on a permanent basis, as provided by some constitutions and in the economic, social, and regional councils of the European Union – to coordinating and regulating agencies jointly organized by the interests and the state after the model of the agencies and councils established in Germany and the United States during the World War I and revitalized by the New Deal or by the (moderately neocorporatist) 'Konzertierte Aktion' of the early 1970s in Germany. A variety of corporatist arrangements in other countries would also fit into this category. The highest level of institutionalization with compulsory participation, binding decisions, and some general jurisdiction has been reached in sectoral interest representation in councils or chambers with delegated public powers, and in the different regimes of institutionalized labor relations with 'tripartite' participation, in many industrial countries. In addition, in the United States and in Europe some of the newly established legal programs for the empowerment of women or minorities, although they do not recognize interest groups, have given some of the respective groups a quasipublic monitoring function.

Secular Changes

At the end of the twentieth century, both the interest groups and the established systems of interest intermediation have been affected by two secular processes of change, first from 'more organized' to 'less organized' politics, since the 1970s, and second from an almost exclusively national frame of reference to a more transnational set, particularly since the 1990s. First, corporatism as well as the quasicorporatist functions of the 'iron triangles,' since the economic crisis of the 1970s, have been significantly weakened by the increased tendencies toward fragmentation and segmentation, of interests and politics, under the impact of decentralization and deregulation, 'new lobbyism,' and the emergence of new public interest groups. This has particularly been the case in the United States. In Europe, the most salient features of this process have been the losses in membership and the declining influence of the labor unions, and the policies and politics pursued in order to reconstruct, and often retrench, the (various types of) social and welfare states (Streeck, 2009).

A second process of change that sped up since the 1990s has significantly added to the transnationalization of interest group politics, within a broader spectrum of restructured constellations of the public sphere, under the impact, particularly, of the use of the Internet, the breakthrough of the 'network society' (Castells, 1996), with all its technological, economic, and organizational potentials, and of advanced globalization and new interdependencies on a worldwide scale. The nation state ceased to be the only (or in a number of areas the most important) addressee of interest groups, and frame of reference of the systems of interest intermediation. The impacts of 'globalization', however, went two ways. On the one hand, it has provoked resistance; triggered processes of fragmentation or regionalization; and given rise to new 'antiglobalist' interest groups, movements, and alliances (Barber, 1995), which now could be organized more easily, less formally, and less contained by national borders.

On the other hand, advancing globalization has reduced the regulatory potential of the nation states, and hence the influence of national interest groups and organizations. At the same time, transnational regulatory regimes have increasingly gained significance, such as in international criminal law, human rights, the rules of the World Bank system, World Trade Organization, fair trade, anticorruption, or labor standards (not to speak of the European Union). All these processes were further intensified by the repercussions of the great economic crisis of the first decade of the twenty-first century, although they were different in different parts of the world (e.g., crisis of the 'neoliberal' paradigm, rising protest organization, increased state interventionism coordinated transnationally). Therefore, on the whole, the agents of influence were encouraged to organize and operate more transnationally, even if the emerging transnational systems of interest intermediation so far have not yet reached the density and the degree of institutionalization of their national precursors (Schneider et al., 2006). The great exception here appears to be the unfolding of the system of interest politics of the European Union, which, after contained beginnings in the agricultural sector (the early shift of influence from the national associations of agriculture to the European interest group Comité des Organisations Professionnelles Agricoles (COPA) is a good example for 'form follows function'), from the late 1970s, has continuously developed into a full-fledged new system of interest representation and intermediation, triggering a whole new industry of social science research (e.g., Eising and Kohler-Koch, 2005;

Greenwood, 2011; Streeck and Schmitter, 1991). During the first decade of the twenty-first century, informed estimates counted around 2500 interest groups and 15 000 lobbyists in Brussels, a bit less than in Washington, DC (estimated between 13 000 and 20 000). Two-thirds of the lobbyists represented European trade federations, consultants, and firms, and only 10% national associations (Berkhout and Lowery, 2008).

Functions for Democracy

Together with the political parties, interest groups are the core agents of structured intermediacy indispensable to the functioning of a free society and a democratic polity. They contribute essentially to the aggregation, articulation, and representation of interests and serve as vehicles for identification, mobilization, and participation, and also as transmission belts for support and legitimation. On the whole, most modern interest groups during the nineteenth and twentieth centuries have contributed to the extension and preservation of liberal democracy, and to social and political changes. The existence of distinct and different organized interests has been a key prerequisite of the recognition of pluralism, for setting up channels and rules for the democratic game, and for checks and balances cf., eg., the 'classics' (Bentley, 1949; Key, 1964; Truman, 1962). Active and dynamic interest groups and 'associations' of all kinds (and under various labels, such as NGO, NPO, CSO) have contributed to consolidating the mechanisms of civil society, and their participatory and mobilizing energies have helped to revitalize political systems in cases of crisis and stagnation.

The essence of these functions has not been affected by the secular changes taking place at the end of the twentieth century, even if the interest groups, like the political parties and the mechanisms and institutions of representative government in general, have come under additional pressure by the rise of new competitors, participatory ad hoc mobilization, fragmented associationalism or deliberative bodies, and the lines between interest groups, social movements, political parties, and service firms for political communication have (again) been blurred more than before. Following the 'cultural turn' in the social sciences, recent research on interest groups has particularly emphasized their strategies for networking (and servicing their constituencies) and their management of communication (Hoffjann and Stahl, 2010; Steiner and Jarren, 2009). However, even in a more complex environment the interest groups have remained key agents of participation, pluralism, and democracy (Beyers et al., 2008; Burbank et al., 2012; Jordan and Maloney, 2007).

Interest groups, however, cannot be considered to be democratic per se in their internal structure, or to defend and promote democracy under all circumstances. In many European countries during the first half of the twentieth century, interest groups, principally of industry, agriculture, and the mobilized crisis-ridden middle classes, substantially contributed to the breakdown and destruction of democracies, and collaborated with the dictators (e.g., in Germany, Italy, and Spain), in particular by disputing the principle of parliamentary representation and the legitimacy of political parties. As, with regard to their primary political function, many tend to be somewhat ambiguous vis-à-vis the particular form of the political order, it is important that interest groups – like political parties – be held responsive and accountable to the general rules of the democratic game, that their performance in the public arena be subject to adequate control, and that, wherever necessary, efforts are made to integrate the regime of interest intermediation into the texture of democratic institutions and traditions (which may be more problematic in the case of groups acting transnationally). In dictatorial regimes, in contrast, interest groups, despite their instrumental function of organizing and occasionally mobilizing the different social sectors around the regime party or movement, in many cases by virtue of their participatory impact, have also been serving as vehicles of incremental liberalization, which eventually produces elite splits, transfers loyalties from the regime, and contributes to its demise. Research into the transitions from authoritarian rule and the consolidation of democracy has also demonstrated that the character of interest groups and the constellations within the 'partial regime' of interest intermediation have an important function for the overall process of democratic consolidation (Schmitter, 1995).

Abstract

In psychology, interest refers to both the psychological state of engagement and a relatively enduring predisposition to reengage particular content (e.g., mathematics) over time. Interest positively influences attention, goal setting, and learning strategies for people of all ages both in and out of school. This article describes characteristics of interest as well as issues of measurement, specifically the need for indicators that account for differences of context, age, and experience. A retrospective case study provides a basis for distinguishing among interest and: motivation, engagement, goals, identity, self-efficacy, self-regulation, attitude, disposition, grit, and mind-set.

Introduction

In everyday usage, interest describes attraction or preference (Valsiner, 1992). However, in psychology, interest refers to both the psychological state of engagement and the relatively enduring predisposition to return to engagement with particular content (e.g., mathematics, music, tennis) (Hidi and Renninger, 2006). Researchers' questions about interest may focus on development, emotion, task features/experience, value, or vocational interest (see Renninger and Hidi, 2011), and can refer to topics, situational interest, individual interest, or four phases in the development of interest: triggered situational, maintained situational, emerging individual, and well-developed individual interest (Hidi and Renninger, 2006; see **Table 1**).

In the following sections, we (1) survey working definitions of interest, (2) describe characteristics of interest, (3) provide a retrospective case study of interest development and use it to distinguish interest from other variables that are often used interchangeably with interest but are distinct concepts, (4) set out indicators for the measurement of interest and its development, and (5) summarize the impact of interest as a cognitive and motivational developmental variable.

Working Definitions

Presumably because of its relation to everyday experience, interest has a number of meanings, even within the field of psychology. Thus, those studying interest need to be clear about their usage and the meaning of others' usage, and avoid creating new terms if at all possible. Here, working definitions of the terms topic interest, situational interest, individual interest, and phases in the development of interest are described, with pointers to the present and/or historical context of their use.

Briefly, topic interest refers to a subtopic of a domain. For example, cells and plants are two topics in biology and a student may be interested in cells but not plants, or vice versa. Topic interest can be either a situational or an individual interest (Ainley et al., 2002).

Situational interest (also known as an earlier phase of interest development, or less-developed interest) refers to the triggering of attention that can occur in both earlier and later phases of interest development. The triggering of interest can be a response to surprise, complexity, novelty, uncertainty, or challenge, which are described by Berlyne (1960) as collative variables. Triggers for attention may also naturally occur in the environment (e.g., a thunder clap), come from the organization of instruction (e.g., hands-on activity), or be self-generated (e.g., strategies developed to stay on task). If situational interest is maintained, it will lead to reengagement over time and to the development of interest. There are two phases of situational interest: triggered situational interest and maintained situational interest (see **Table 1**).

Individual interest (sometimes called personal interest, a later phase of interest development, or more-developed interest) refers to interest that is developed beyond situational interest. It is characterized by voluntary and frequent reengagement with a discipline over time, the ability to pursue the discipline independently, and the ability to seriously engage the discipline by asking and seeking answers to curiosity questions (questions that are novel to the learner even if they are not novel to the discipline; see Renninger, 2000, 2010). There are two phases of individual interest: emerging individual interest and well-developed individual interest (see **Table 1**).

The Four-Phase Model of Interest Development describes phases in the development of interest that were identified based on a review of the empirical literature (Hidi and Renninger, 2006; see **Table 1**). The model includes two phases of situational interest and two phases of individual interest.

Phases (not stages) of interest characterize the development of interest across age levels and contexts, both in and out of school. They are described as phases because using the word 'stage' would suggest that interest develops as an invariant sequence, which is not always the case. Although interest can continue to develop, it can also go dormant if novelty and challenge are unavailable (Bergin, 1999). The continued development of interest depends on the quality of interactions with other people and of conditions in the environment (e.g., the nature of tasks, the presence of tracking, and press for achievement) (e.g., Frenzel et al., 2010).

Researchers often study either situational or individual interest as a specific phase in the development of interest. They also research earlier (situational) phases and later (individual)

Table 1 The four phases of interest development (Hidi and Renninger, 2006): definitions and learner characteristics

	Phases of interest development			
	Phase 1: Triggered situational	*Phase 2: Maintained situational*	*Phase 3: Emerging individual*	*Phase 4: Well-developed individual*
Definition	• Psychological state resulting from short-term changes in cognitive and affective processing	• Psychological state that involves focused attention and persistence over an extended period, and/or reoccurs and persists	• Psychological state *and* the beginning of relatively enduring predisposition to seek reengagement with particular classes of content	• Psychological state *and* a relatively enduring predisposition to reengage particular classes of content
Learner characteristics	• Attends to content, if only fleetingly • Needs support to engage from others and through instructional design • May experience either positive or negative feelings • May or may not be reflectively aware of the experience	• Reengages content that previously triggered attention • Is supported by others to find connections among their skills, knowledge, and prior experience • Has positive feelings • Is developing knowledge of the content • Is developing a sense of the content's value	• Is likely to independently reengage content • Has curiosity questions that leads to seek answers • Has positive feelings • Has stored knowledge and stored value • Is very focused on his or her own questions	• Independently reengages content • Has curiosity questions • Self-regulates easily to reframe questions and seek answers • Has positive feelings • Can persevere through frustration and challenge in order to meet goals • Recognizes others' contributions to the discipline • Actively seeks feedback

phases of interest, or the development of interest across one or more phases.

Characteristics of Interest

Regardless of the type of interest on which researchers focus, there is general agreement about five of its characteristics (Renninger and Hidi, 2011). First, interest is content or object specific, meaning that interest is directed toward a particular activity, field of study, or goal. As Krapp and Prenzel (2011) explain, the learner is interested in something or someone.

Second, interest involves a relationship between learners and their environment. Interactions with others and the available resources of the environment can determine if interest continues to develop or not. The connections that the learner makes lead to deepened experience, described as magnification (Silvia, 2001) or the developing of knowledge and value components in the learner's interest development (Renninger, 1990, 2000).

Third, interest is composed of affective and cognitive components, namely affect or feelings, value, and knowledge (Hidi and Renninger, 2006). These components are present in each phase of interest, although affect may be high and knowledge and/or value may be more minimal in earlier phases of interest development. As interest develops, the levels of knowledge and value increase.

Fourth, learners may be unreflective and unaware of their interest while they engage. For example, a history student could feel excited and attentive when studying geography, but might not recognize that feeling as interest. If the student has a less-developed interest for history, he or she might not even consider it possible that interest could be triggered; whereas, a student with a more-developed interest for history might be so involved that he or she is not reflectively aware of his or her interest.

Fifth, interest has a physiological/neurological basis. Humans are hardwired to engage in seeking behaviors (Panksepp, 1998; see also Hidi, 2012). With the development of interest for particular content, they seek resources and opportunities that allow them to stretch present understanding. Characteristic behaviors include asking and seeking answers to curiosity questions (questions novel to the person who is asking them) (see Renninger, 2000, 2010).

Retrospective Case Study

In the retrospective case study that follows, we describe a student whom we call Eva. Her interest in mathematics is detailed and then analyzed in order to provide a context for considering the meaning of interest in relation to (1) its development and to (2) other terms that are distinct from interest, but often used as though they were synonymous.

Overview

During high school, Eva developed an interest in mathematics and completed seven levels of mathematics in 4 years. However, when she began high school, her only goal was to complete calculus for college applications, and she had little, if any, interest in mathematics.

Eva was the youngest child in a home where she played games that involved problem solving, such as chess and sliding-block puzzles, and engaged in a lot of open-ended LEGO construction. She liked school mathematics assignments when she was working on them but did not look forward to mathematics. She did not realize she was offtrack in learning

mathematics until she was in sixth grade and her parents and a number of the parents of other students got together and demanded that the school teach their children the mathematics they needed for middle school.

In seventh grade, the students were given sixth- and seventh-grade-level textbooks and were expected to work independently to complete them. They were to finish one section of the textbook per week, and could work on any section that they wanted at any time. Eva recalls that her teacher checked to see that students completed the sections assigned the first month and did not check the homework after that. However, Eva's mother would sit with her everyday after school and help her to work through problems in the textbooks.

Eva remembers being a little excited when her mother used colored blocks to help her learn positive and negative numbers, but she also reports that any excitement she experienced was short-lived. She was just doing what she was told to do. She did not do any extra work on problems that she did not understand, nor did she think about mathematics in her free time.

In ninth grade, Eva's counselor told her that she needed to take a course in algebra, and preferably a course in trigonometry, in order to go to college. She was initially placed in the second half of algebra, but was dropped back into the first half of the course because she struggled and did not put very much effort into learning the concepts. The first half of algebra was a good fit to Eva's mathematics abilities and the teacher was very welcoming and receptive of her timid questions. In fact, the support and encouragement that she felt led her to enroll in the second half of the course right away, even though she had not planned to take the second half of algebra until the following year.

The next term was pivotal. Eva describes this teacher as making the concepts of algebra 'come alive.' She appreciated that he provided clear explanations and she knew he liked teaching algebra. He was also the AP Calculus BC teacher, and in the course of teaching, he provided examples of how algebra was used in calculus. Eva describes herself as fascinated by algebra and excited to go to class everyday. She also reports that she began feeling confident about her mathematical abilities.

By the end of the year, Eva was determined to work her way up to AP Calculus BC. She was curious about calculus, and had come to love the challenges of mathematics. By the time Eva enrolled in trigonometry, she was voluntarily spending extra time on her mathematics homework and thinking about other ways to approach the problems assigned. Outside of school, she started reading articles about mathematics (e.g., about Fibonacci sequences in nature, such as the spirals in pinecones) and played with making circular arcs like the spirals in her artwork. Mathematics had become fun to think about. She observes that she 'sort of forgot' that she was supposed to be completing mathematics classes in order to go to college; it was only on hindsight that she realized that to someone else her interest in mathematics, and the number of courses she completed, might seem extraordinary.

Analysis

Eva's experience illustrates the range of conditions that can trigger and support interest to develop as well as differences between having a less- and a more-developed interest. It is not inconsequential that: she chose to engage games that involved problem solving in her free play as a child; her parents demanded that there be more of a mathematics program in the school; her mother would sit with her each day to support her to do her mathematics homework; she was placed in a classroom matched to her level of readiness to do mathematics; one teacher was receptive to her timid questions; and another teacher made connections between algebra and calculus, supporting her to see how topics of mathematics are related and how her studies of mathematics might unfold.

In recounting her experience, Eva does not think of her free play at home as a form of problem solving, or that its connection to mathematics was possibly dormant through middle school because of the way she was introduced to and taught mathematics. She reports being somewhat interested when she was doing mathematics in elementary school, but also says she only did her mathematics homework because she was supposed to. She did not think that she was very good at mathematics and does not think she began to understand mathematics as a discipline until she took algebra. In other words, Eva is not aware that she might have had an interest in mathematics before the second term of algebra, and even then, the fact that she enjoyed working on mathematics in and out of school is something that she had not thought about. On reflection, she remembers that her attention was triggered but not sustained by the colored blocks or the value her parents held for mathematics. However, her interest was triggered and then maintained by the support she received from her high-school teachers.

Interest, Engagement, and Motivation

When learners have interest, or are supported to develop interest, they are engaged. They are committed to learning and participating; they also are motivated in that they have identified goals that they seek to accomplish (see Järvelä and Renninger, 2014). Eva had little interest in mathematics. She could be said to have been engaged, in that she was going through with requirements to participate and self-regulate (e.g., Christenson et al., 2008). She could also be considered motivated. She had a goal to complete enough mathematics so that she could be competitive in her application to college, and she weighed the expectancies of task interest, utility, importance, and the analysis of cost in relation to her given goal (e.g., Wigfield et al., 2006).

Eva's approach to mathematics changed once her interest for mathematics was both triggered and sustained. There had been multiple potential triggers to support her to develop an interest in mathematics (e.g., her mother's help, the goal to complete enough mathematics to be competitive for college), yet Eva's sense is that it was the combination of these and the help she received from her teachers to both work with mathematics and see the tangible connections between the topics she was working with that made the difference.

Although interest can be supported to develop at any age and in any context, there are differences in the types of supports that learners need at different ages. For example, younger children are often ready to explore unfamiliar disciplines and

activity. However, beginning around 8–10 years of age, when learners begin comparing their accomplishments with those of other peers (e.g., Harter, 2006) or to their own capacities in disciplines that are already developed interests, additional and different supports to continue to persevere may be needed (Renninger, 2009; see also Durik et al., 2015).

Interest, Goals, Identity, Self-efficacy, and Self-regulation

Research has demonstrated that there are reciprocal relations between interest and other variables including goals (e.g., Harackiewicz et al., 2008), identity (e.g., Renninger, 2009), self-efficacy (e.g., Hidi et al., 2002), and self-regulation (e.g., Hidi and Ainley, 2008). When learners have a less-developed interest for a discipline, they may or may not be aware that their interest could be triggered and developed, or that their interest has been triggered. They are often unable to set goals for themselves in working with the content of potential interest or to participate productively without guidance from other people (e.g., Eva's mother sitting with her as she did her mathematics homework) or from the design of the tasks that they engage (e.g., the open-ended assignment to complete texts independently in any order that the student chose was not appropriate for Eva).

Although learners with little interest may be on task and thus appear to be engaged, their learning requires effort and they are less likely than those with more-developed interest to persevere to get through frustrations associated with completing challenging tasks. Like Eva, learners with little interest also have little self-efficacy (e.g., Bandura, 1997), or confidence about their abilities to successfully accomplish tasks in a content area that is not already a developed interest. They may be timid about asking questions, if they seek help at all. They also may or may not be in a position to self-regulate (Sansone et al., 2012).

When learners have a more-developed interest, on the other hand, they can be expected to have and/or to be developing the attention, goal setting, and learning strategies needed to seriously engage content. Like Eva following the second half of algebra, they can be expected to expend effort without it feeling effortful (Dewey, 1913), and can be expected to have developing feelings of self-efficacy about working with mathematics and growing abilities to self-regulate so that they can persist to work through challenging problem sets.

Interest, Attitude, Disposition, Grit, and Mind-set

Once Eva took the second half of the algebra course, her attitude, or belief, about mathematics was positive (e.g., Ajzen and Fishbein, 1980). Her interest was maintained and it had begun to develop. However, attitude differs from interest in several respects. First, attitude is a belief. Interest is not a belief, although a learner can have beliefs about identified interests. In the earliest phases of interest development, a person may or may not be aware that his or her interest has been triggered. Interest is a psychological state during engagement with particular content and in later phases a relatively enduring predisposition to reengage that content. Second, research on attitude distinguishes between those with positive or negative feelings. Interest, in contrast, is described as being triggered by both negative and positive emotions (see Hidi and Harackiewicz, 2000). Finally, whereas liking is an indicator of attitude, it is not considered to be sufficient as an indicator of interest, nor is it synonymous with interest because 'liking' may or may not cooccur with wanting and learning (see Berridge et al., 2009; Hidi, 2012).

Although Eva developed an interest in mathematics, the disposition (e.g., Gresalfi, 2009), or habit, to persevere to complete the tasks on which she was working was present even when her interest had not yet developed. She was able to learn, and her disposition meant that she did her homework, participated in class, and persevered (Carr and Claxton, 2002). However, the difference in the quality of her work with mathematics before and after her interest developed was marked. Before, she worked to complete mathematics assignments and did not think about them after they were completed. Once her interest developed, she was engaged in thinking about mathematics and exploring mathematics in reading and in art, as well as in her mathematics class.

Eva also had grit, or the ability to persevere (Duckworth et al., 2007). Initially, Eva persisted to complete the work that was assigned because it was expected of her. Once her interest was triggered and began to develop, she began to develop a passion for the subject and she persevered because she wanted to. As Fulmer and Frijters (2011) report, individuals who have a more-developed interest in a task are more likely to both enjoy it and persist through challenge, whereas those with less-developed interest are more likely to avoid challenge. With the shift to developing an interest for mathematics, Eva was thinking about and doing mathematics voluntarily and was continuing to develop her understanding of mathematics whether she had assignments or not.

It may be that because Eva was supported to have a growth mind-set (Dweck, 1999), a belief that she could learn, that she completed the assigned mathematics and had the disposition and grit to persevere (see Dweck et al., 2011). Unlike interest, mind-set is a belief about self and basic qualities that can affect behavior – Eva felt that she could learn and did the work that was required. Unlike mind-set, interest is not a belief; rather, in earlier phases of interest development, a learner may or may not be reflectively aware that his or her interest has been triggered and that it could be developing, and in later phases of interest, a learner can be so engaged that he or she may not be aware of the extent of this involvement (see Renninger and Hidi, 2011). Like interest, mind-set is considered to be malleable. However, interest is context dependent and mind-set is studied as a more general characteristic of the learner.

Because interest develops through interactions with context, the development of interest is idiosyncratic. Its development is dependent on the nature of potential triggers and whether these are recognized and responded to as opportunities. The development of interest has been found to reliably vary for groups based on participant characteristics: age (e.g., Neitzel et al., 2008), discipline (e.g., Denissen et al., 2007), gender (e.g., Baram-Tsabari and Yarden, 2009), goals (e.g., Harackiewicz et al., 2008), and feelings of self-efficacy (e.g., Durik et al., 2015).

Eva's situation is not the same as the next person's, and yet there are regularities in the phases of the development of her

interest. Retrospective analysis makes it appear easy to identify shifts in the phases and characteristics of interest. However, it is challenging to measure interest prospectively, especially in the earlier phases of interest development when a person may not even consider that he or she may have or could develop an interest, and cannot necessarily respond accurately on self-report measures about his or her behaviors. In the next section, we survey current approaches to the measurement of interest, and provide some detail on the nature of indicators that together have been used to assess later phases of interest development and which, in their absence, define earlier phases.

Measurement

There are no established or agreed-upon methods for measuring interest and its development, as is the case with many motivational variables (see Murphy and Alexander, 2000). Moreover, the gaps between the ways in which interest is conceptualized and the methods used to study interest are not necessarily recognized (Krapp and Prenzel, 2011). This may be because empirical reporting does not typically involve researchers in describing the relation between their conceptualization and their choice of measures (Renninger and Hidi, 2011). It may also be because the questions on which interest researchers work range from questions about interest as a dependent variable to the impact of interest as an independent variable. Also, the disciplinary contexts, learning environments, and age groups on which this research is focused vary, which necessarily affects the methods used because different groups may interpret questions and respond to methods differently.

In this section, we outline sources of data on interest, indicators of developmental interest, and give examples of items that can be used to distinguish between less- and more-developed interests. We focus on less- and more-developed phases of interest given the idiosyncratic nature of interest development. The development of interest can occur quite quickly and may also involve slow and steady change (see Renninger and Riley, 2013).

Sources of data for studying interest have included artifacts (e.g., lab notebooks), class enrollment, computer log data (e.g., log-file analysis, data collected in online modules), experience sampling, in-depth semistructured interviews, running ethnological records, self-reports, forced choice, Likert ratings, open-ended items, teacher or researcher observations of participation, think-alouds, and/or video. However, the most common source of information is the survey (e.g., Chen et al., 1999; Eccles et al., 1993; Linnenbrink-Garcia et al., 2010; Marsh et al., 2005; Rotgans and Schmidt, 2011; Schiefele et al., 1993).

Of note, although four phases in the development of interest have been identified retrospectively (e.g., Lipstein and Renninger, 2007) and there are current efforts to identify all four phases of interest prospectively in domains such as second-language learning (Cabot and Chouinard, 2012) and by generating multidimensional interest profiles (Ely et al., 2012), the idiosyncratic nature of interest mandates clarity about the indicators selected and consideration of how they apply in the settings being studied. Present understanding suggests the utility of indicators that reflect developed forms of interest in a discipline and the use of this information as a basis for assessing how developed interest is.

Four indicators of participants' developed interest include whether their engagement is frequent, deep, voluntary, and independent relative to their other engagements (Renninger and Wozniak, 1985; see the discussion in Renninger and Su, 2012). While other motivational variables such as goals, self-efficacy, and self-regulation and learner characteristics such as attitude, disposition, grit, or mind-set are related to and/or can be expected to affect interest, these variables are not the primary targets of the four indicators of developed interest.

Assessments that focus on interest development ideally address activity with particular content (e.g., mathematics) over time, but may not. They also would assess comparison among the activities of and contents engaged by the learner (rather than between-learner comparisons), learning settings in which both independent and collaborative work/play can be observed, and open-ended activity (unprompted activity). They may also need to acknowledge that depending on age and/or experience, learners may not be meta-aware of their activity, which affects their ability to provide self-reports. In completing surveys, they also may work either with outside Likert items (e.g., 1's and 5's) or inside (e.g., 2's and 4's), and/or may not interpret item stems in the way that researchers intended (see Frenzel et al., 2012).

Drawn from different age groups of participants and learning contexts, examples of the types of data that can provide information about each of the identified indicators include video and running written records of young children in free play who also completed experimental tasks (Renninger, 1990), online questionnaires, log-file analysis, artifact analysis, and follow-up interviews employed to study teachers working online with modules (e.g., Renninger, et al., 2011), and survey and think-aloud data from a study of middle-school-age students working with mathematics and reading tasks (e.g., Renninger et al., 2002).

Frequency of engagement can be assessed using running records that provide consecutive and distributed instances of participation, log files of participant work online that can be used to track the types and frequency of particular participation (e.g., in discussion, with resources), and surveys that include ratings about the particular activity being studied (e.g., mathematics) in addition to ratings of other types of activity (e.g., reading, baseball) to provide confirmation of relative frequency of engagement.

Examples of data that allow assessment of the depth of participant engagement include the exploration of a preschooler who begins trying to identify at what point a block will slide down the slope of a roof he or she is building. Measurement of work with tasks can address the presence of developed exploration, accuracy, and/or complexity.

The indicators of voluntary and independent reengagement provide a check on whether a participant is likely to reengage voluntarily or independently; it is not expected that all engagement is voluntary or independent. Rather, it is expected that engagement is not just in response to assignment or expectation (voluntary) and that it is not only social or

undertaken with others. Data that indicate that the participant is reengaging work with particular content voluntarily may be most easily assessed with behavioral data that allow multiple opportunities for the learner to reengage. During free play, this might include notes about whether engagement occurs by choice when it is neither required nor a response to social opportunity such as being invited to a birthday party. Online, collected data from artifacts or in log files allow content analysis of discussion participation, journaling, and/or problems worked as part of assigned work. On a survey, when reengagement cannot be studied directly, participants can be asked how likely they are to engage particular activity outside of school that is not assigned (e.g., How likely are you to do math problems that are not assigned? How likely are you to talk about math outside of work you need to do for class?).

Independent reengagement with particular activity can be assessed using video and running written records of free play by identifying consecutive and distributed instances of engagement with different play objects, and online, using log files that allow tracking the type of participation (e.g., discussion, use of resources, etc.). On surveys, independent reengagement can be determined by using Likert or open-ended questions that ask about the content of study and also about other activities that provide a contrast, and/or direct inquiry about whether the respondent works on the task independently.

Features of participant groups and learning environments vary and require adjustment of how indicators of interest development are employed. Thus the decision to use one or another data source and the adjustment of each of the four indicators need to account for the age of participants, the content or context of activity including interactions with educators and independent activity, multiple domains or contents, the learner's meta-awareness of interest, the learner's self-representation, the level of granularity of interest under study, and the timescale of the study.

Impact

Regardless of their particular focus, studies of interest indicate that developing interest is beneficial to motivation, engagement, and learning. They also indicate that interest can be supported to develop at all ages.

The development of interest has been repeatedly found to beneficially affect learner attention, goal setting, learning strategies, and achievement. Interest influences whether and how learners pay attention to content (e.g., McDaniel et al., 2000; see Hidi, 1995). As Durik et al. (2015) observed, learners with little interest who need to learn content are learning for reasons other than interest. At least initially, they may have difficulty attending to the task as it is intended and may need triggers for interest that guide their attention to particular features. Triggers for interest can help the learner make connections to the content and then sustain these connections long enough so that learning can take place (Ainley et al., 2002). Palmer (2009), for example, reported that there are a number of different types of situational interest associated with classroom activity, but for his high-school students, novelty was the strongest trigger for interest. As Durik et al. (2015) and Renninger (2010) also pointed out, the triggers that work for learners may differ based on the learners' phase of interest.

The presence of interest indicates the likelihood that learners have goals, or curiosity questions that they want to answer, even if these are not clearly or fully articulated. In later phases of interest, it can be expected that they will work independently to address these. As Harackiewicz et al. (2008) report, goal setting appears to be proportionally related to a person's level of interest. Learners with more-developed interest are more likely to set goals for themselves and work to realize these goals than are learners with less-developed interest. Interest also beneficially affects learning strategies. With the development of interest, the learner engages in deeper levels of processing, employs a larger range of strategies, makes decisions about when and which strategies to employ, and is able to persevere and reorganize an original plan as his or her work with a task unfolds (e.g., Schiefele and Krapp, 1996; Renninger et al., 2002).

Finally, interest and achievement are often linked, presumably because of the tailored practice that often accompanies a developed interest (e.g., Azevedo, 2013), the kind of practice that allows the learner to continue to develop his or her skills, further solidifying the basis for the ongoing development of their interest. Wigfield and Cambria (2010) called for specific consideration of age-related development in learners' interest, values, and goals in achievement outcomes, noting that it is critical to understand the relation among these variables over time. For example, in a cross-sectional study of learners between 6 and 17 years of age, Denissen et al. (2007) reported a stronger association between self-concept of ability and school grades when grades are also considered, despite findings indicating that interest is coupled with self-concept of ability. The strong relation between interest and self-concept of ability is consistent with the expectancy–value model (Eccles et al., 1983), in which the relation between expectancy and value and between self-concept of ability and interest are expected. The relation between interest and self-concept of ability is also consistent with discussions in which value has been attributed to factors other than performance. Denissen et al. (2007) also pointed out that students who perform well sometimes do not have a developed interest in the discipline (e.g., Renninger et al., 2002). However, Sansone and her colleagues (Sansone et al., 2012) have reported that grades may not predict level of learner achievement because interest can also lead a learner to focus on mastery and not necessarily on performance.

While findings to date point to the role of interest in improving learner success, how achievement is conceptualized both by the researcher and by the learner is critical, as is how achievement and interest are assessed. Data reported by Frenzel et al. (2012) suggest that learners can respond to the same item differently depending on age. Wigfield and Cambria (2010) pointed specifically to the need for conceptual clarity in items on surveys and in interviews, additional methods to complement data provided by self-reports, and person-centered methodological approaches (e.g., cluster analysis and profile analysis) in addition to variable-centered analysis.

Next steps in refining our understanding of the effects of interest involve several challenges related to measurement. Given that interest is a content-specific motivational variable, measurement needs to account for differences of interest for particular content areas, as well as for age- and experience-related development. Measurement that distinguishes between learners with less- and more-developed interests may also be useful, as there is increasing evidence that these are often distinct profiles due to the idiosyncratic nature of interest development. In this article, we describe four indicators that can be adjusted and used together with a variety of methods and data sources to assess less- and more-developed interests across age groups and contexts. Researcher agreement on indicators of interest development could help to offset the potential complications of measurement invariance introduced by differences of context, age, and experience.

Acknowledgments

We are appreciative of the thoughtful comments we received on earlier drafts of this article from Mary Elizabeth Talian and Suzanne Hidi. We thank Melissa Running for her editorial assistance. We also gratefully acknowledge support for our work from the Swarthmore College Faculty Research Fund.

Interest: History of the Concept

Abstract

As a central notion for understanding human behavior, the concept of interest emerged in early modern European political theory. It was part of the skeptical view of human affairs that informed the secular approach to politics and government, which arose anew in the Renaissance. In the course of the seventeenth century, the concept entered a variety of other intellectual genres as well, and obtained a new and crucial significance by becoming linked to a theory of civil exchange. To view human behavior as interest driven was not merely considered a matter of political realism, it came to be valued as socially beneficial as well. This new conception of human society was subsequently elaborated by political economists and utilitarian philosophers. From the early nineteenth century onward, the conceptual development has occurred mainly in debates accompanying the rivalries between academic disciplines. Interest was associated primarily with economic theories, which have been emulated, enlarged, corrected, as well as contested in other disciplines.

While modern social science is inconceivable without some notion of interest, the actual concept has a long and complicated history of shifting meanings. In this relatively brief article, these changes will be highlighted by following the main stages of this conceptual development. In doing so, the notion will be understood in its specific sense, abstracting from the development of similar notions (such as utility or preference), but without isolating the concept from its place in more encompassing theoretical frameworks. The most significant changes in the history of the concept are inseparable from its relations to other concepts and to the transformation of broader theoretical structures. For a proper understanding of these changes, it is important, furthermore, to realize that they are related to reconfigurations of the intellectual groups that have been the carriers of the intellectual change.

Understanding human behavior as driven mainly by (self-) interest is not in itself very noteworthy. The idea can be found in many ancient traditions of thought, both religious and secular. Most of these understandings, however, were normative rather than descriptive or explanatory. Forms of self-interest were condemned as sinful, as socially disruptive, and they were generally opposed to either religious or military virtues. Elites in agrarian societies valued religious devotion and military prowess, that is, types of behavior distinct from agricultural labor and trade or commerce. If (self-)interested behavior was not condemned as illegitimate, it was at best tolerated within very narrow social boundaries, and subsumed to more virtuous modes of behavior.

As a central term for understanding human behavior, the word interest emerged in political writings during the early modern period. It was part of the skeptical view of human affairs that informed the secular approach to politics and government that arose anew in the Renaissance. In the course of the seventeenth century, the concept entered a variety of other intellectual genres as well, and it obtained a new and strategic importance by becoming linked to a theory of civic exchange. To view human behavior as interest driven was not merely considered a matter of political realism, it now came to be valued as socially beneficial as well. This view was subsequently elaborated by political economists and utilitarian philosophers. From the early nineteenth century onward, the conceptual changes occurred mainly in debates accompanying the development of academic disciplines. Interest was primarily embedded in economic theories that have been emulated, enlarged, corrected, as well as vividly contested in other disciplines.

The Politics of Interest

The word interest, derived from the Latin *inter esse*, originally referred to procedures for compensation in Roman law. The expression *id quod interest*, meaning 'that which matters' or 'that which counts', could be applied to a variety of claims in this respect. The specific meaning of taking rent on loans was directly related to the legal notion of compensation. Interest in this particular sense came into use in many European languages during the fifteenth century, commonly as a euphemism for usury (Fuchs, 1976; Hirschman, 1992).

The more general meaning of the term emerged in the beginning of the sixteenth century. Interest then referred to the more general sense of advantage and to the human propensity for seeking benefits. It was part, not of an economic discourse, but of the skeptical anthropology and the secular approach to statecraft, appearing systematically for the first time in the work of Francesco Guicciardini (1483–1540). Guicciardini, one of the most perceptive political theorists of Renaissance Italy, frequently observes in his *Ricordi* (1512/30) that 'self-interest' prevails in nearly all human beings. This applies especially to successful leaders and others who do well in life; they always have their 'own interest in mind and measure all their actions accordingly'. Guicciardini adds, however, that 'true interest' does not necessarily reside in pecuniary advantage; it pertains, more often, to honor and to the art of knowing how to keep a good reputation.

The general meaning that Guicciardini gives to the term allows him to use it for matters of government as well. Where particular interests are in conflict with the 'public interest',

Guicciardini advocates the primacy of the latter. The conceptions of Guicciardini and his contemporary Niccolò Machiavelli (1469–1527) were developed more fully in the reason-of-state literature, which flourished in Europe around 1600. For one of the leading theorists, Giovanni Botero (1544–1617), 'reason of state' meant 'reason of interest', and state interest ought to be the supreme rule of conduct for princes and statesmen. In this view, religious and constitutional matters were to be treated as instrumental issues. For the ruler, interest of state is the only legitimate principle of action, and this interest is defined in opposition to both the interests of other states and the passions of the ruler. Control over people demands self-control; passions and other disorderly appetites need to be replaced by a rationally (ob)serving state interest.

Interests thus came to be seen as the principal motive of human behavior and as the only realistic rule of political conduct. From a predominantly critical concept, directed against ecclesiastic and humanistic virtues, it had gained a more positive meaning. While preserving its amoral connotations, interests appeared to be a more stable and more reliable motive than the passions (Hirschman, 1977). The French Huguenot leader Henri de Rohan (1579–1638) expressed this view in his influential *De l'Intérêt des Princes et des États de la Chrétienté* (1638) by stating that "princes order their people around and interest orders princes around." The prince can be deceived, his council can be corrupt, only 'interest does not lie'.

It was through the translation of Rohan's work that the term 'interest' became established in the political vocabulary in England. And it was from the political scene that the term was transferred to the market place and came to be applied to private behavior (Gunn, 1969).

In the early modern political literature, interest was not merely an analytical term. Interests were indeed perceived as the predominant motive of human behavior, but political advisors stressed that interests had to be observed in a rational and calculating way. This was not because human beings were considered to be rational decision makers, but because of the strategic advantages of rational calculation. The prudential weighing of costs and benefits was a behavioral norm for political elites rather than a form of motivational reductionism (Holmes, 1995).

Contours and Consequences of Exchange

From the political literature, written by counselors and diplomats, the notion of interest entered a variety of other intellectual genres in the course of the seventeenth century (Heilbron, 1998/2001; Lazzeri and Reynié, 1998). Among these other discourses, natural law and moral philosophy stand out; in both cases, interest-driven behavior came to be related to new conceptions of politics and society.

In modern natural law, interest was part of a foundational argument. The anthropology of the skeptics had given a seemingly universal role to self-interest and more in particular to self-preservation. Natural law theorists treated this factual observation as a natural right. On the basis of the fundamental right to assure one's self-preservation, they built a system of moral and political obligation, which was intended to overcome religious orthodoxy as well as the relativism of the skeptics.

For natural law theorists such as Thomas Hobbes (1588–1679) and Samuel Pufendorf (1632–94), people are motivated primarily by self-love. But the consequences of their view differed fundamentally. For Hobbes, a strong state was the only alternative for permanent and violent conflict between selfish individuals. Pufendorf constructed more of a historical argument. Human societies arise out of individual needs. Upon this assumption, he proposed a scheme of societal development, culminating in a form of sociability proper to 'commercial society'. Commerce at the time referred to exchange or traffic in the general meaning of these terms, not specifically to trade. The idea of a 'commercial society' designated a relatively pacified order within which various realms of exchange had been established. Contrary to Hobbes, Pufendorf thus envisioned a form of sociability based essentially on the ties of interest-based exchanges (Hont, 1987).

The very idea of a social order emerging out of the self-interested acts of individuals was more systematically elaborated in seventeenth-century French moral philosophy. In a series of remarkable essays, collected in his *Essais de morale* (1671–78), the Jansenist moral philosopher Pierre Nicole (1625–95) explained how human society could be well ordered and prosperous without assuming any religious duties or prescribing secular virtues. Following the Augustinian tradition, Jansenist theology made a strict distinction between the 'city of man' and the 'city of God'. The radically separated realms were founded on two mutually exclusive drives: self-love and love of God. Nicole and some other Jansenists and writers close to them (Pascal, La Rochefoucauld) sought somehow to adapt their uncompromising outlook to the demands of worldly life. Many of them were members of the salon of Madame de Sablé and were like Nicole searching for a *modus vivendi* for Christians who were forced to live in a corrupt world. Looking for an intermediary route between pious retreat and worldly corruption, Nicole proposed what is probably the first consistent model of commercial society.

The Hobbesian image of a war of all against all, Nicole argued, is valid only in the very beginning of humankind. Since each human being is a threat to the other and no one wants to be a victim, people unite with other people. To affirm their union, laws are established and punishment is instituted for those who violate the laws. Fear of death is therefore the first restraint on self-love. Once open violence is excluded, human beings are forced to use artificial means to satisfy their desires. These artificial means are all forms of exchange. The result of this process is a civil society, which – given the corrupt human nature after the Fall – could not be better organized, even if true religion is banned. Human traffic alone, established and regulated by self-love, had produced this result.

From the point of view of God, human society meant corruption, but from the point of view of human beings themselves, the establishment of human civility is the best possible achievement. Given the fact that very few people are prepared to withdraw from society, Nicole added that 'enlightened self-love' could be considered the most effective policy in human affairs.

For Nicole and his fellow Jansenists, human beings could not be credited with any virtue. As in the maxims of

La Rochefoucauld (1613–80), they depicted what seemed virtuous (courage, love, friendship) as being but a refined expression of self-interest. In the words of La Rochefoucauld: "Interest speaks every sort of language, and plays all sorts of roles, even that of disinterest." Since human virtue is a kind of narcissistic illusion, self-interested exchange was the most realistic alternative for the threat of civil war and a sufficient basis for an orderly society.

The argument about civil society as a process of generalized exchange on the basis of self-interest also provoked an historically important counterargument. In his critique of Jansenist anthropology, the philosopher François Fénelon (1651–1715) asserted that 'disinterestedness' was not beyond human reach. Human beings may actually experience pure and 'disinterested' love, which is close to a state of selflessness. The love of God is the highest form of this disinterested love, but Fénelon acknowledged more worldly forms as well, especially in the spontaneity of children. The term 'disinterestedness' and the argument about its possible significance were formulated in the context of a theological dispute, the *querelle du pur amour*, but it soon gained importance in other social domains, first in aesthetics, somewhat later in other areas. When Immanuel Kant at the end of the eighteenth century defined esthetical experience as disinterested pleasure, *interesseloses Wohlgefallen*, he took up the notion of disinterestedness, which British moral philosophers like Shaftesbury had taken from the French dispute over Jansenism.

Political Economy and Utilitarianism

Many of the economic and utilitarian arguments advanced in the eighteenth century were derived from these seventeenth-century writings in moral philosophy. Well before Adam Smith, Pierre de Boisguilbert (1646–1714) transformed Nicole's reasoning into the more specific idea of a self-regulating economic order. On the condition that this order could function freely, it would tend toward an equilibrium. That being the case, Boisguilbert spoke of 'laissez-aller', advocating to let this natural order run its course, thus unambiguously announcing the liberal consequences of Nicole's model for the economic realm (Faccarello, 1999).

Bernard Mandeville's tale about 'private vices' as the actual source of 'public benefits' was similarly rooted in the work of French moralists. It was not disinterestedness or self-denial that produced civil society, but vanity, avarice, and ambition. Inspired by Mandeville (1670–1733) and his predecessors, Adam Smith (1723–90) famously pointed out that it is not from the benevolence of the butcher, the brewer, or the baker, that we expect our dinner, but from their regard to their own interest. "We address ourselves, not to their humanity but to their self-love, and never talk to them of our necessities but of their advantages." Society, according to Smith, "may subsist among different men, as among merchants, from a sense of its utility, without any mutual love or affection."

The historical significance of Smith and other classical political economists was that they transformed the argument about self-interested exchange into an economic theory of self-regulating markets and the idea of harmonizing economic interests through the 'invisible hand'. But when the general argument about exchange narrowed down to a mechanism of markets, the political questions implied in the doctrine of interest reemerged. Utilitarianism was one of the attempts to rethink the political and moral issues involved.

Emerging in the eighteenth century and becoming an intellectual movement with Jeremy Bentham (1748–1832) and James Mill (1773–1836), the utilitarian system was built on the principle that every human being seeks pleasure and avoids pain. Human conduct is universally guided by the ideas and feelings that are associated with either one of these emotions. This behavioral principle was applied not only to individuals, but extended to the polity as a whole. Like individuals, governments should promote the amount of happiness and reduce the amount of pain. Moral arithmetic, based on the principle of the greatest amount of happiness of the greatest number, thus provided the means for assessing the utility of public institutions and initiating political reform.

The rise of political economy and utilitarian philosophy provoked several counter movements in the decades around 1800. In their opposition to the French revolution and the ensuing waves of democratic reform, conservatives appealed to the luster of tradition in order to counter the cold-blooded politics of interest. Romantics similarly found ways to reaffirm the power of the passions.

Disciplinary Social Science and Interdisciplinarity

When the social sciences during the nineteenth century became university disciplines, theories of interest were associated specifically with economics, which – with the exception of Marxism – was increasingly separated from the other social sciences. The broader framework of moral philosophy disintegrated and made way for a disciplinary division of labor. John Stuart Mill (1806–73) redefined the status of political economy by arguing that while different causes operate in society, some of the more powerful causes need to be studied separately. Political economy was legitimately restricted to the phenomena based on the desire of wealth and the law that a greater gain is preferred to a smaller. In Mill's view, political economists do not deny other motives, but merely abstract from them; self-interest is a methodological construct rather than a behavioral reality.

During the 'marginalist revolution' of the latter decades of the nineteenth century, the plea for scientific abstraction was combined with the postulate of maximization (Demeulenaere, 1996; Hausman, 1992). Economic behavior was modeled as rational calculation aimed at maximizing utility. This approach, which formed the heart of the neoclassical program, allowed much of the formal and technical developments that have characterized mainstream economics ever since. Self-interested behavior was now treated by means of a mathematical technique of maximization under constraint. With Vilfredo Pareto (1848–1923), the domain of economics was redefined as the study of choice or optimization, and in Lionel Robbins's definition economists study "human behavior as a relationship between ends and scarce means that have alternative uses."

While this definition is, in principle, applicable to all forms of human behavior, many economists were well aware of the limits of their approach. For Pareto, neoclassical economics had

a limited validity since many aspects of human behavior do not meet the conditions of rational calculation. In addition to the restrictions of their behavioral assumptions, many economists acknowledged the fact that the 'invisible hand' and *laissez-faire* politics were no panacea. For a variety of reasons, market outcomes can be at odds with the welfare of large parts of the population, and instead of repeating the elusive metaphor of the invisible hand, economists specified the functioning as well as the dysfunctioning of markets (Medema, 2009).

Since its inception during the first half of the nineteenth century, sociologists have generally contested purely economic and utilitarian approaches (Swedberg, 2005). Auguste Comte (1798–1857) introduced the word sociology to overcome what he saw as premature specialization and misguided generalization. Interests were an important motivational force, but so were the human affects. In his later writings, Comte coined the term 'altruism' for all nonegoistic forms of behavior, arguing for its primacy over self-interested behavior. Other sociologists differentiated human behavior in other ways, some of them elaborating richer notions of interest than merely individual, economic interest (social, collective, or public interest; vested interest; symbolic interest). Parallel to undertaking historical and empirical inquiries into the various forms of behavior and sociability, sociologists reacted critically to the abstract and exclusive nature of *homo economicus*. Emile Durkheim (1858–1917) and François Simiand (1873–1935) argued against the 'unrealistic abstractions' of economic theory, advocating a positive and more empirical approach that was not unlike that of institutional economics. Max Weber (1864–1920) proposed a broader understanding of interest and rationality and integrated these into a general typology of social action. Weber introduced 'ideal interests' aside from material interests, and distinguished instrumental rationality from value rationality. In addition to affective and traditional action, instrumental rationality refers to a means–end relationship, while value rationality pertains to choice as derived from values.

While the academic division of labor between the social sciences became much stricter during the middle part of the twentieth century, it has been increasingly contested since the 1970s. Economic theories and modeling procedures expanded into many areas, which were previously seen as the territory of other disciplines. Chicago economists like Gary Becker argued that the economic approach to human behavior, that is, the "combined assumptions of maximizing behavior, market equilibrium and stable preferences", should be used relentlessly and unflinchingly for all types of human action in all historical periods. Public choice economics and the 'law and economics' movement similarly extended notions of self-interest and maximization to the political and juridical sphere. In political science economic approaches to voting, political parties and government became mainstream, and rational choice, more generally, became the common denominator for a broad area of interdisciplinary work (Heap et al., 1992).

The expansion of economics into noneconomic domains in the latter part of the twentieth century was, be it on a more modest scale, accompanied by a movement in the opposite direction; psychologists, sociologists, and organization theorists gradually invaded the domain of economics, proposing alternative accounts for core issues of economic theory. Psychologists established a wide variety of behavioral phenomena, which contradict the assumptions of rational choice thus contributing to the establishment of 'behavioral economics'. Sociologists have repeatedly shown how cultural beliefs and institutional structures shape (economic) behavior and its outcomes. Diverse and varied as these contributions may be, they have at least demonstrated that the technical sophistication of economics depends on assumptions that can be questioned and contested on empirical as well as on theoretical grounds.

Enduring Ambiguities

Since its early uses in Renaissance political theory, the concept of interest and its terminological derivatives (self-interest, group interest, public interest, vested interest, and ideal or symbolic interest) have been part of what may be broadly considered the materialist tradition in the social sciences. But this realistic and hard-nosed orientation is itself divided over a number of fundamental issues. The development of the notion of interest uncovers at least three enduring ambiguities.

First, the term interest and its equivalents can be used for interpretative purposes in accounting for observable behavior; they can also be used in a normative way for defining what rational behavior is. In the former sense, interest refers to an explanatory and empirically testable principle; in the latter, it merely designates a logically possible and perhaps desirable course of action. The ambiguity of serving both descriptive and prescriptive functions has persisted ever since the origins of the term. Second, interest can refer to material advantages as well as to political, cultural, and symbolic benefits. If the broader understanding of interest is accepted, the ideas of rational calculation and maximization become problematic, since it is unclear how costs and benefits in various domains can be rigorously compared with one another. In the absence of an overarching metric, people have multiple interests without being able to rationally compare their relative benefits. Far from being exceptional, uncertainty is a defining characteristic of human choice. Third, actors may pursue their interests by relying on rational calculation, but they also do so on the basis of a process of socialization in which choice is not 'rational' in the economists' sense, but bound up with habitualization leading to the practical mastery of a social game (Bourdieu, 1990). In the former case, interest is part of rational choice theory; in the latter, it is not.

Interests in Sociological Analysis

Abstract

A sociological study of interests involves a definition of the concept of interests, since they can be said to vary socially. It is also concerned with the relation between interests (notably economic ones) and other human ends, for instance the values that lie behind any social order. Therefore, it implies a methodological debate about human agency: should it be considered as intrinsically selfish or unselfish, and how does one interpret any behavior that departs from the pursuit of selfish interests? This methodological debate is related to an appreciation of the different kinds of rationality that can be associated with human behavior. This article will describe mainly the way classical sociology has conceptualized the issue of interests, and the contemporary developments of those classical positions.

It is not an easy task to define the notion of interest. Throughout the tradition of sociological analysis, it is often referred to without further specification (Swedberg, 2005). In ordinary language, there are two general meanings of this particular concept: the first is that of an agent's special commitment toward some kind of object, or activity, like music. This meaning can be studied by sociology as far as it is concerned with tastes or cultural practices. Although not specifically selfish, those interests in this broad sense can nevertheless sometimes lead to conflict among persons, when the success of their realization for someone leads to an opposition to others' desires, values or interests: for instance if a street artist tags a wall in order to display what he perceives to be his artistic ability, the neighbors can feel seriously injured by such an aesthetic expression. This is a conflict of interests, although no economic or selfish dimension is directly involved. It is more a matter of aesthetic disagreement. But it is important to note that actions based on values can lead to conflict of interests.

The second and more important meaning is the one that implies some kind of selfishness in the notion of 'self-interest.' This is mainly the case with 'economic' interests, those concerned with the appropriation of scarce goods. But this idea can also be extended to noneconomic goods, like power or prestige. Wealth, power, and prestige have a common aspect: they are such that the increase of their amount for one person can often lead to a decrease of their amount for another person (what we call a zero sum game). It is not possible inside a group that prestige or power increases simultaneously for everyone, since those are relative positions. On the contrary, it is possible that wealth increases simultaneously for everyone inside a group, although the opposite can also be true: someone's wealth can increase to the detriment of another's. The two situations are very common in the social world, although people often tend to believe that only or another tends to prevail. Those selfish interests are generally described in terms of costs and benefits, or utility, with two main difficulties: first, costs and benefits cannot always be translated in monetary measures, and therefore measured at all; second various people do not necessarily have the same costs and benefits, so that the notion of costs and benefits is not something easily predictable of peoples' choices. For instance a drug consumer does not have the same costs and benefits as someone who is not interested at all in drugs. Therefore, should we consider that someone is devoted to maximize his or her utility, or maximize his or her benefits and minimize his or her costs, this would not allow us to predict his or her actual choices: costs and benefits vary according to various persons, and they vary according to social settings. Put in another way, interests can be seen as often dependent on social norms (the ones for instance that prescribe to smoke or not to smoke) or alternatively as the basis of social norms (the interest in health would lead to a norm prohibiting smoking).

Sociology and Economic Interests

The Problem of Social Order

Economics has been described as a science of human interests, when they are considered apart from any other motive, and in particular the interest for wealth. This definition is explicit in Pareto's general statement on the division of work inside social sciences. According to this description, what should the role of sociological analysis be regarding interests? Three major problems come to the forefront of the discussion.

The first one is that of social order. Any economic activity occurs within a social framework, made up of varied institutions, rules, and rights. A market, for instance, depends on property rights that allow people to exchange their goods. There are two options here. The first one is to explain this framework in terms of interests, following the tradition of Hobbes and Hume. There is a trend, especially in contemporary sociology inspired by economics, to try to revive this kind of explanation of social norms in terms of interests (Coleman, 1990). The main idea is to consider that in specific situations people have an interest in adopting social norms (for instance property rights) without which their basic interests would be threatened. Norms are based on interests and are protective of them through some limitation of their extension. This idea can be conceptualized in terms of theory of games, in a reiterated prisoners' dilemma situation that leads to the emergence and adoption of norms. In this case there are shared given interests which are the basis of the explanation of the emergence of social norms. The purpose of the norms is to reinforce the satisfaction of the same interests. However, it should be noticed that an important

part of contemporary economic reflection about property rights insists on the historical dimension of property rights that cannot be reduced to an emergence in prisoners' dilemma situations (North et al., 2009). The more important variable from a historical point of view is the relative weight of various interests, whereas in standard theory of games inequality of position regarding interests is not taken into account. Moreover, theory of games rests mainly on the postulate of the similarity of interests, whereas people, as we have seen, do not necessarily share a common conception of interests.

But the major part of sociological analysis has tried, on the contrary, to define a specific attitude toward social order that *cannot* be reduced to interests. If social order and the norms and values associated with it do not stem from individual interests, where do they come from?

Three major classical sociologists have tried to describe the problem of social order as the main area, in social life, where it seems that interests alone cannot suffice to produce the norms that unify people into a society. Moreover, social order has the role of limiting selfish interests. Comte, first, in a radical attack against what appeared to him as an 'abstract' view, namely that of social contract and economic exchange, stressed the existence of a social consensus foreign to any calculation, and prior to any economic exchange. Following Comte, Durkheim built all his sociological theory on the assumption that individual interests cannot be seen as the root of social solidarity. In a Kantian fashion, he understood morality and social norms as a repressive force against individual interests. But, in opposition to Kant, he did not find the roots of such obligations in an individual rational sense of morality, but rather derived it from a specific social level that exerts coercion upon individuals. Parsons, in his attempt to build a general theory of society, continued this tradition. He stressed the existence of common shared values on which economic interests depend. The main point that these three authors made is that selfish interests cannot always lead to cooperation. These same interests can also lead sometimes to opposition and conflict among individuals. Hence, the social primacy of cooperation should not be based only on interests. It needs a firmer basis. It is located in the functioning of the social system as such that puts pressure on individuals.

These three authors can fairly easily be grouped under the so-called holist tradition, which insists on the role of a specific social level irreducible to individual decisions, which exerts a specific constraint on individual decisions. But even in the tradition of methodological individualism, there has been a similar trend to refer interests to the values behind them that allow or restrict their development. This is notably the case of Max Weber's theorization of interests who insists on the fact that typical economic attitudes are influenced by religious beliefs. The two traditions, however, can be seen to have in common the fact that interests, related to preferences, often depend on social values, and that any interest intervenes within a social situation.

Economic Attitudes

The second classical problem is that of economic attitudes themselves. In the economic main tradition, these attitudes are generally considered from a nonhistorical point of view, as relatively constant human tendencies. For instance, in his description of economic equilibrium, Pareto makes no direct reference to any historical evolution or change of economic attitudes. For him there are only random distributions of different attitudes toward interest among different people (Pareto [1916], 1963). The *homo economicus* figure is not, in this perspective, a historical one, but a theoretical construction of typical constant attitudes in economic life (and beyond, in political life for instance when politicians try to gain more power). In most of the sociological tradition, this has been seen as irrelevant, since economic attitudes do vary historically, at least partially. Therefore, various attempts to explain the logic of these changes can be found. Such is the aim, for instance, of Mauss's ([1925]1954) *Essai sur le don*, although the gift and the potlatch rituals involve many self-interested attitudes. More generally, sociological analysis tries to relate interests to the background values that encourage or discourage them (and often constitute them). In fact, there are two aspects to be stressed from this standpoint.

The first is that the very notion of what is to be considered as an interest for an individual can vary socially. For instance, Mauss tries to show that in archaic societies there is no real interest in personal consumption, but there is a strong interest in social prestige, that is not derived from consumption, but from gifts. Therefore, the social importance of gifts can be opposed in one sense to a self-interest oriented toward personal consumption. But on the other hand, this importance of gift is linked to the interest in an increase of personal prestige. It is certainly not a purely altruistic behavior.

The second level is that, any kind of interest being admitted as such (for instance interest in wealth), there are always social values that reinforce its deployment or conversely restrict its expression. For instance, loans on interest can be authorized or forbidden in a given social community. Weber is thus famous for having, in his work on the Protestant ethic (Weber [1904–5], 1974) and on the economic ethic of world religions, stressed the influence of religious orientations on economic ones. He links the development of capitalism to a complex religious background specific to the peculiarities of western cultural tradition. Demagicalization, universalization, and moralization of relations among people, commitment to an ascetic lifestyle, and interpretation of worldly success as a sign of eschatological salvation are the key religious elements that can contribute to explaining capitalism's rise in Western societies. These religious elements are joined to other values, namely the general importance of rationality, and its effects on other institutional contexts, like the extension of rational legal systems. The specific modern capitalist attitude cuts itself from its religious roots: it becomes an acquisitive trend in a society oriented toward constant increase of goods rather than satisfaction of stable needs (Weber [1923], 1981).

There is, however, another element important in the analysis of economic attitudes: the description of tastes and preferences that lay behind interests. Parsons and Smelser (1956), for instance, in a general theorization of the relations between economics and sociology, insist upon the fact that the economic preferences that constitute interests are rooted in common social values. This point had been made earlier by Durkheim: the fact that a specific meat is allowed to be eaten

or not depends on social norms and is the basis on which individual preferences are defined. The analysis can apply also to the very constitution of economic markets and the value of profit making. Polanyi (1944) has stressed the importance of other norms than norm markets that precede them historically (norms of reciprocity and norms of redistribution), the orientation toward profit being a modern specific norm instead of a permanent human attitude.

Somehow surprisingly, this idea that economic preferences depend, at least partially, on social values and norms, can be equally found in contemporary economic analysis: beyond the idea of costs and benefits, utility maximization is derived from individual preferences. There is no utility as such, but only sets of individual choices that constitute individual utility. Therefore, individual utility can depend on social norms (this is obviously the case, for instance, for food or clothes preferences). The key issue is whether the notion of utility can be related to stable transcultural human preferences, or should be always seen as dependent on specific social settings.

The Scope of Interests

The third classical problem is that of the extension of the role of interests in social life. Economics mainly studies the production and exchange of scarce goods. But interests arise in other fields, such as political conflict, family attitudes, crime decisions, educational choices, drugs consumption, etc. The problem will be then to understand how far an analysis in terms of interests can go to explain social phenomena.

The article so far has stressed the importance of the social background that narrows or enlarges the field where interests play a role, and has also indicated that, from a sociological point of view, the very definition of interests mostly depends on a social valuation of some kind of ends.

But to this description should be added the opposite trend, the one that insists on the role of typical standard interests in several aspects of social life. This move does not only refer economic exchange to selfish interests, nor does it try to explain social values or institutions in terms of interest, but it also sometimes considers that even beliefs can be referred to interests. This can be done either with a critical stance, or only with an explanatory noncritical scope.

In the tradition of Marxist analysis, the critical attitude toward social order is related to the revelation of hidden interests not only behind oppressive institutions that serve the interests of the powerful, but also behind common moral or political beliefs and ideologies which are derived, in their proper constitution, from interests: people believe what they believe because they have an interest in doing so. The main difficulty of such a conception is that it does not take into account the specifically cognitive side of any ideology that cannot be so easily reduced to noncognitive contents and to some kind of material interests. It can be said that when people believe something, there is always a cognitive dimension of the belief that makes it acceptable for the believers given their social situation and their level of information, and the fact that it is hard to believe something that could appear to be false or completely unjustifiable. Naturally, however, beliefs can be influenced by interests and equally various unconscious biases.

But the extension of the scope of interests can also intervene without any critical intention: it is only then an effort to show that attitudes in some areas apparently removed from any economic dimension, can be interpreted in terms of interests, not only social norms, but also attitudes toward marriage, children, voting, etc. Becker's (1976) work on family or Posner's (1981) work on law and justice are representative of such ambitions. Supporters of this central role of interests in social analysis as well as its opponents have named it 'economic imperialism.' It depends on a definition of what are 'costs' and 'benefits,' against values. For instance, in fertility decisions, a child has an expected financial cost, but it has also a 'psychological' benefit; the problem is that, financial costs and psychological benefits being not equally measurable, and not easily comparable to each other, any decision can be said to be maximizing utility, since any decision is necessarily a balance among financial costs and psychological decisions. To say that it is a maximizing decision is therefore tautological, and certainly not predictive of the various choices, and explanatory of the differences among the various choices, unless we can explain why psychological benefit is not equally appreciated.

A Methodological Divide

Altruism and Selfishness

It can be said that there is a common assumption shared by the two traditions that try to explain social order in opposed fashions regarding interests: the selfishness of individuals. Individuals are considered to act according to their interests because they are selfish. This common assumption leads to two alternative results, as we have seen. The first is to consider that social order and social norms can be explained in terms of social interests, through reiterated prisoners' dilemma situations. The second is that it is not possible to do so, but, since there is a social order as well as something like a morality, which leads individuals to act morally, in an unselfish manner, it has to be referred to something different from interests.

But why should individuals be considered selfish? There are basically two different reasons for this. The first is empirical and arises from the evidence of the selfish attitudes that prevail in economic exchange, where there is a huge tendency to avoid systematically letting someone's else interest prevail over one's own.

The second element is methodological: since commitment to social values is to be explained in a way that is not tautological, it seems convenient to try to show that these norms derive from a sense of interest, that should not, for its part, be explained.

Durkheim admits straightforwardly that individuals as such are selfish when they are taken alone, but he does not justify this assumption, taken from economics. This assumption is, however, at the core of his effort to describe a specific social coercive level that should explain why individuals act in an unselfish way on certain occasions. His argument could be worded as follows: "Individuals are selfish; sometimes they devote themselves to others, but since others are just like me, I should have no reason to prefer them to myself; therefore, it is not to them that I show my respect, through my moral behavior, but to society, as a distinct entity from any

individual" (Durkheim [1906], 1996). But this statement rests on the idea that such altruistic behavior is always strange. One gives another individual what one has denied oneself, despite the fact that this other being is just another version of oneself not worthy of such an attitude.

But in fact, most often, this so-called altruistic behavior does not correspond to this description. Usually, it intervenes in three different scenarios in social life. The first relates to symmetrical attitudes of reciprocity. In this case, there is an admission of the idea that different individuals should have the same rights, and therefore, be allowed to have the same opportunity to pursue their own interests within a common framework. The respect of the right of the other is not seen as the altruistic renunciation of one's self-interest for the other's benefit. It can be derived from the acknowledgment of the fact that both individuals can be granted the same rights since they have the same interests. It is not that one favors the other at the expense of oneself. It is that everyone can understand, precisely, that since someone's interest should not systematically prevail upon the other's, the solution to this problem is the adoption of norms of reciprocity. A related analysis can be found in Harsanyi (1969). Norms of reciprocity can be based either on an utilitarian device or on the belief that one's interest should not unilaterally and systematically prevail over the other's interests. The solution to such situation is the recognition of symmetrical rights.

The second case for altruism occurs when a stronger or wealthier person helps a weaker or poorer one. But, in this case, it is obvious that if people renounce their own interests in favor of someone else, it is precisely because they are in a position to help someone else who does not have the same means. This indicates that it is not another equivalent self that is helped, but someone who is in a worse position. Such attitudes are common in social life. They can derive from the pursuit of prestige, but, more commonly, from a sense that some people need assistance, and that it is right to help them in specific situations (but not in others).

Third, it is true that sometimes there is a 'sacrifice' of the self in favor of others. Durkheim insists strongly on this kind of situation. But it could be understood, also, by considering the specific position of the person: if the captain of a ship is legally considered to be responsible for a vessel's safety because of his or her specific competence, it is therefore consistent for the captain to remain on board until everyone has evacuated. Such sacrificial attitudes are today analyzed by psychological literature (Elster, 2009).

All this means that it does not seem absolutely necessary to assume that there is some global social force behind the individual restrictions to self-interest. It is possible to understand actors' self-limitations of interest by their ability to understand the logic of a situation and the need for social rules. Therefore, three positions can be described. The first one is an individualistic and utilitarian position, that interprets most of human actions in terms of selfish interests, as in the case of Coleman's sociology.

The second is a nonindividualistic and nonutilitarian position. As we have seen, it rests upon the idea that, as individuals are selfish, and naturally committed to their own interests, the fact that they sometimes act in an altruistic manner should lead to the recognition of a specific social (not individualistic) level that is responsible for such a change of attitude and pressure on self-interest.

But since it is not obvious that individuals should definitely be considered selfish and only devoted to their own interests without the intervention of a superior social force, it seems possible to introduce a third methodological position, individualistic but nonutilitarian. Actors would have then to choose to favor their interests, or instead to avoid satisfying them, because they would be able (maybe 'rationally') to understand the appropriate course of action regarding different situations.

Rationality and Interests

It is important to introduce here the notion of rationality, which has a multisided relationship with that of interest. The classical notion of rationality that prevails in economics is an instrumental one. It designates the choice of adequate means toward ends. The idea of rationality relates to this 'correctness' of the choice of means. The important point is that ends are not integrated in this sense of rationality that concentrates on the adequacy of the choice of means.

But the rational choice model, highly influential both in economics and sociology, is not entirely clear (Demeulenaere, 1996) in this respect. On the one hand, it is officially maintained that ends, i.e., interests, are not rational by themselves, rationality being reserved to the choice of means. But on the other hand, the qualification of rational behavior in economic and sociological literature is generally applied to an attitude that does follow selfish interests, and denies respect to any kind of value or social norm that would go against them. There is also another ambiguity. On the one hand, interests are not considered to be substantial ones, as they depend on individuals' choice. But on the other hand, interests are described as substantial: money or wealth, power and prestige. Sometimes rational choice is described in terms of narrowly defined specific interests (which makes it at least predictive and falsifiable). Sometimes, it is described as a very general intentional dimension of action, which can only be opposed to unconscious attitudes.

Thus it is not clear whether this rational choice model is strongly normative or not. It would be so if it stressed that individuals are rational only if they follow their interest, in the selfish sense. But this assumption is very costly for two reasons. The first is that it is not obvious that obeying one's own interests should be the only possible rational choice. The second is that many individuals do not have the impression that they are not rational when submitting to a norm that cannot be referred to interests. On the contrary, they believe they have reasons for doing so.

Axiological Rationality

Therefore, it seems possible to introduce, in sociological analysis, a third point of view that maintains the principle of rationality, without restricting it to the pursuit of interests or to the limited choice of means toward ends. This principle of rationality should allow the actor to discriminate between interests that deserve to be followed and those that should be avoided.

How should we define this axiological rationality (Boudon, 1997)? The main point is that it would show the reasons actors have to act in a specific way, the reasons being not necessarily their interest. Boudon, for instance, shows the importance, in the voter's attitudes, of normative aspects that should not be reduced to the actor's narrow scope of interest. Those normative aspects are not arbitrary as they can be related to a system of beliefs that seems acceptable to actors regarding their general aims. Voters know that, in a large-scale election, their individual votes have no influence on the result. But they know also that other voters are aware of the same fact. If they all abstain from voting, they will lose the benefit of the democratic system. Committed to that system, they understand the importance of voting, even if it is costly in the short run and seemingly inefficient.

Such a theoretical interpretation of the actor's behavior should thus expand the concept of rationality and depart from a narrow positivistic attitude where the ends (including interests) can never be interpreted in their own rationality.

Intergenerational Justice

Paul Kelly, London School of Economics, London, UK

Abstract

Intergenerational justice poses challenges for standard theories of justice and morality because it presupposes the absence of the usual interpersonal connections that explain moral relationships. Can one use the analogy of a contract between two parties that could not interact, or where one side has an ineradicable ability to impose nonreciprocal harm? Can one have obligations to improve the welfare of those who don't exist and whose potential existence is conditional on the actions proposed? This article explores the ways standard theories such as contractarianism, utilitarianism, and communitarianism accommodate the claims of future people. It explores issues such as the nonidentity problem and various 'repugnant conclusions,' before challenging the skeptics with a threshold conception of universalism that supports environmental sustainability.

This article surveys the problem of intergenerational justice but does not address all ethical problems posed by future generations. This problem can be viewed from the perspective of how we can have obligations to those in the future and what kind of things we might owe to those in the future. The first three sections review the way traditional theories such as contractarianism and utilitarianism deal with obligations to the future. The problem of asymmetry, the nonidentity problem, and the issue of 'repugnant' conclusions are considered, by focusing on the work of contractarians such as David Gauthier and John Rawls, and consequentialists such as Derek Parfit. The final section reviews the work of Avner De-Shalit and Barry, McMahon, and Meyer who attempt to overcome these skeptical challenges and reassert the idea of obligations to the future. Avner De-Shalit uses the idea of a transtemporal constitutive community to explain the motivation for obligations to posterity. Barry, McMahon, and Meyer defend a threshold version of universalism that is indifferent to issues of temporal continuity in determining our obligations of justice. The article concludes with a review of Barry, McMahon, and Meyer's claim that our chief obligation to future generations is encompassed in the need to pursue environmentally sustainable development as part of a threshold conception of justice.

Intergenerational justice refers to the negative and positive obligations one generation owes to another. The concept of a generation is essentially indeterminate as there is no point at which a single generation stops and another begins. Within any single population a number of generations will coexist. Intergenerational justice does not refer to relationships of right and duty between different generations within one temporally continuous population. The obligations of young to old or old to young are matters of distributive justice. Intergenerational justice refers to the relationships of obligation, right, or benevolence that ought to exist between groups of people who are not temporally continuous or to that set of issues which apply to noncontinuous populations, in the same way that international justice applies to populations that do not spatially overlap.

The fact of nontemporal continuity explains the problem of intergenerational justice. Many philosophers argue that the absence of temporal continuity casts doubt on the possibility of justifying claims of obligation or right between generations. De George argues that as future people do not currently exist they cannot be the bearers of anything least of all rights or moral claims. Discussions of intergenerational justice focus on two sets of questions: first, how do we explain obligations between nontemporally continuous populations and second what obligations might we have to future generations? This article examines the bases of these doubts about extending the idea of justice to apply to the relationship between nontemporally continuous populations and then conclude with an assessment of what we might owe to posterity.

Contractualism and Asymmetry

Contemporary discussions of distributive justice are synonymous with the resurgence of contractarian thinking under the influence of philosophers such as Rawls (1971) and Gauthier (1986). The contract device is used for thinking about distributive questions in circumstances where the parties disagree about ultimate moral principles. If we cannot base our obligations to one another by appeal to a common standard such as utility maximization, we can use the idea of a rational bargain or reasonable agreement as the basis for distributive norms and obligations. The idea of a contract is a thought experiment that can be used to legitimize principles rather than an actual agreement process that groups of people have to collectively engage in. However, even as a hypothetical device the idea of a contract (in both versions of the theory) poses a major problem because of the asymmetrical relation between the participants in intergenerational cases.

The 'mutual advantage' theory argues that distributive principles can be derived from a rational bargain between participants in a cooperative venture, such as market society or political community. The issue of justice only arises when certain circumstances of justice obtain. If each individual could get everything they wanted without cooperation there would be no need for principles of justice. The circumstances of justice are threefold. First, (roughly) equal power among the parties. What one lacks in strength they can make up in guile so no one is guaranteed always getting their own way. Second, moderate

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63036-2

scarcity of goods and motivations obtains, so that social cooperation is necessary or at least in the interest of all. Finally, while all benefit from the existence of social cooperation, the participants are interested in the distribution of its benefits and burdens. As rational agents each has an interest to maximize their share of the benefits but minimize their share of the burdens of cooperation.

The problem for the 'mutual advantage' theorist is that the circumstances of justice do not unequivocally obtain between noncontinuous generations. If we use the idea of the contract within one generation we can make sense of the idea of rough equality of power and reciprocity as the key motivations for accepting the distribution of the benefits and burden of social cooperation (although we might still argue that this is a morally inappropriate way to think about justice). Yet when we extend this idea to noncontinuous generations the weakness of the method becomes apparent. In what way can we both speak of ourselves and future generations as part of the same 'cooperative' venture? If we just concentrate on the rough equality of power we can see how there is an asymmetrical relation between the generations. Take an issue such as energy policy. A present generation can unilaterally impose significant costs on future generations such as the management of toxic or nuclear wastes. I leave aside a further case where the consequences of a present decision are so egregious as to prevent there being a future generation. Does stopping potential people coming into existence constitute a harm or injustice? It is clearly possible for a present generation to take such choices without any possible negative consequences from the future generation except perhaps disapproval and poor historical reputation. The present generation is able unilaterally to affect the interests of a future generation, whereas a future generation cannot unilaterally affect the interests of the present generation, hence the asymmetry. Without rough equality of bargaining power any contractual agreement will simply reflect the advantage of the stronger party, in this case the present generation. If this is so, the contract does nothing more than allow the present generation to pursue its own interests taking account of the future only when its own reputation is at stake and when this is of higher value than any other present interest such as standard of living. Because of the asymmetrical relationship underlying an agreement it is unclear how the present generation could be motivated to assume obligations to the future given the motivational assumptions of 'mutual advantage' contractarianism. The contract not only does not generate obligations to the future, but would appear to generate reasons for ignoring such claims.

The 'impartialist' theory departs from many of the key features of the 'mutual advantage' bargain just considered. Rawls' theory introduces the idea of a hypothetical original position in which the participants deciding which principles of justice should shape the basic structure of their society as a fair system of social cooperation, are shrouded by a 'veil of ignorance.' The point of the veil of ignorance is to filter out the possibility of exploiting 'positional' advantage or inequalities of bargaining power. By denying agents behind the veil of ignorance, information about their particular circumstances and goals, and allowing them only general knowledge about society, Rawls constructs an impartial choice situation. Rational self-interest plus ignorance delivers impartiality and fairness.

Rawls' theory is a thought experiment designed to test the fairness of candidate principles of justice. The contract with the veil of ignorance is designed to model a fair choice situation. However, once again the asymmetry problem arises. The agents behind the 'veil or ignorance' are denied information that will prevent them from pursuing their own interests at the expense of each other. The agreement is effectively between members of a single generation. What is to stop the participants choosing principles in order to maximize the condition of the worst off currently in existence that will at the same time worsen the situation of those not yet born? In order to bring future generations into the agreement Rawls posits an additional motive for the participants. They are expected to reason as representatives of families who are assumed to have a concern for their descendants. Heads of families provide the intergenerational link that overcomes the asymmetrical relations between future generations. The problem with this strategy is that it merely concedes the problem of asymmetry and the inability of the contract device to generate adequate obligations to the future. At best the additional motivational assumption gives those in the present generation a reason to take account of future generations. It does not establish an obligation to future generations in the way that the contract does establish obligations within one generation. The addition of the extra motivational assumption provides a noncontractarian reason for taking account of future generations. In effect it assumes precisely what it is supposed to provide, namely a reason for taking account of the interests of future generations.

While contractarian arguments have been central to the development of current theories of distributive justice, they seem singularly ill-equipped to deal with issues of justice between generations because of the asymmetrical relationship between even hypothetical bargainers. This is a point acknowledged by Barry, one of the most significant defenders of a neo-Rawlsian contractarianism (in Dobson, 1998b). The key relationship of reciprocity and the equal ability of the partners to affect the interests of each other do not apply in the case of temporally noncontinuous generations. To overcome this, the contractarian has to appeal to noncontractarian reasons.

The Nonidentity Problem

A further ground for skepticism which is related to the asymmetry objection, but which has implications beyond contractarian arguments is the nonidentity problem. This problem has been given its most forceful statement by Parfit (1984). And it is as applicable to theories such as utilitarianism as it is to contractarian theories of justice.

The nonidentity problem draws on a paradoxical implication of the intuitive response to issues of intergenerational justice. Assume that policy makers are making decisions about technologies that deplete environmental resources or cause global warming. These decisions involve questions of intergenerational justice because they do not merely distribute the benefits and burdens of social cooperation within generations but also across generations. Any policy that unilaterally worsens the conditions of future generations

by depleting nonrenewable resources without suitable compensations for the future might be deemed to involve an intergenerational injustice as it sacrifices the interests of future generations to serve our own temporary interests. In this case the injustice consists of harming the interests of future generations by denying them opportunities or by unilaterally imposing costs upon them. Against this a skeptic might respond that our intuitive concern for the future does not withstand critical scrutiny and that we should discount the interests of future generations in determining between environmental policies.

The argument claims that only harms to assignable individuals constitute cases of injustice. An action becomes a case of injustice when it involves harm to the interests of an individual agent or groups of individuals. But if we turn to the issue of appraising environmental policies it is far from clear that they do distribute harms to assignable individuals.

Whichever environmental policy is chosen will have complex consequences for the future, many of which are indirect. One such consequence is on the procreation decisions of particular populations; that is, on who should come to mate with whom. The nonidentity problem depends upon the assumptions that any decision to procreate at one time rather than another will result in the birth of different people. The fact that I was born at the time I was and in the place I was in part made me the person I am now. If I was born either earlier or later my experiences would have been different and therefore I would have been a different person. If this claim is true then any policy which affects people's behavior will have implications for the identity of future generations. Thus, an environmental policy that forces me to use my car less and travel more on public transport may be responsible for me meeting my future partner and therefore albeit indirectly for any future persons who result from our relationship.

The important point is that whichever policy is chosen will result in different future populations and not simply different levels of welfare for the same potential population. But if different populations result from different policy choices then does it make sense to talk about obligations of intergenerational justice? We can argue that a policy of resource depletion does not involve any issue of intergenerational justice because it does not harm the interests of any assignable individual. After all whichever individuals do find themselves bearing the burdens of our choices only exist as the people they are because of choices made by us in the past. If we had chosen otherwise they would not have existed at all, but rather some other group of persons would have existed. For the contractarian the problem of showing how assignable individuals are harmed by our choices undermines the claim that we can do injustices to people in the future, and this fact renders the whole idea of intergenerational justice deeply problematic. But the problem also applies to utilitarian theories that explain the idea of injustice in terms of worsening the welfare of individuals. We cannot, for example, argue that a future population would have a higher welfare if we had adopted a policy of conservation than if we had adopted one of resource depletion for either policy would result in different populations. The issue would then become one not of whether population X had a welfare level of a or b, but whether population X should exist or whether population Y should exist. The utilitarian can respond to this claim but only at the expense of opening themselves to certain repugnant conclusions.

Utilitarianism and Repugnant Conclusions

The idea behind the nonidentity problem is that intergenerational obligations must be person regarding, that is because obligations are owed to assignable individuals. But as we have seen, as the identity of individuals in the future is itself dependent upon present actions, the idea of harming or benefiting future generations becomes problematic. Utilitarians – those philosophers who believe our most fundamental obligation is to promote, either total or average, welfare – often reject the person-regarding view of moral obligations by claiming that overall welfare is prior to questions of its distribution (see Stearns, 1972). For the utilitarian we have an overriding obligation to promote utility or welfare and this avoids the nonidentity problem because we can assess overall outcomes irrespective of the identity of the recipients of utility or welfare. This strategy raises a number of important issues when applied to intergenerational questions, but its most striking consequences arise from its application to population policy.

If we have a primary obligation to promote or maximize welfare and this obligation is prior to any obligations to assignable individuals, then we are inevitably faced with the question how many people should there be? This utilitarian obligation to promote welfare has direct implications for individual procreative decisions. Before considering whether to conceive a child or bring it into the world a couple will need to consider the impact of this decision on overall welfare. We can consider the impact of this procreative choice on either average or total welfare.

Let us first consider the case of average utility. Here we are required to consider the impact of our procreative choices on the average level of utility across the relevant population. If our society is a prosperous and happy one and the addition of further members who, although happy, would be slightly less happy than the average, then their impact would be negative.

In such a case average utilitarianism would counsel against conceiving such a child. Such a way of conceiving procreative decisions might seem suspect, but often we do apply such reasoning in thinking about population policy. Some utilitarians consider draconian population policies are justified by average utility. However, opponents of utilitarianism argue that such an approach to procreative questions is wholly inappropriate because social welfare is a morally irrelevant consideration.

Average utilitarianism does not merely have implications for whether we should allow the birth of happy children who are merely less happy than average, it also has implications for those who exist but are less happy than the average. Consider a population of 10 people two of whom are miserable while eight are happy. If we add to this consideration the fact that there is no hunger in the society so that the eight would not gain in utility if the two were removed, we could still increase the average utility by removing the two. However, we could then make similar judgments within the eight until we were left with a very small population perhaps numbering only two in which there was no difference in average utility. In existing

populations there are always groups whose elimination would, other things being equal, increase average utility.

What happens when these arguments are applied across populations, as in the case of intergenerational justice? If we accept the premise of the nonidentity argument, namely that the policies we pursue will affect the identity and size of future generations then using the average utility argument we can engage in some interesting trade-offs. If we are concerned about a policy of conservation versus one of depletion we can reason as follows. A depletion policy would have a large negative impact on a large population but a relatively low impact on a smaller future population. As long as the impact diminished the fewer people there were to be affected, we would satisfy our utilitarian obligation. This could easily be achieved by coupling the depletion policy with a draconian population policy among our existing population, such that the average utility of the small population x is greater than the average utility of population y that would have resulted from the policy of conservation. The point here is that we can make one of the aspects of the nonidentity problem a policy objective, in order to justify our depletion of resources. As long as we can manipulate the size of future populations by regulating procreative decisions we can pursue almost any policy without harming the interests of future generations.

Average utility results in some questionable conclusions, does total utility fair any better? In the case of individual procreative decisions the issue becomes one of the duties to maximize happy people. As long as each child being born is happy to some degree they contribute to the total sum of happiness. It need not be the case that they are happier than their parents only that they are happier to exist than not to exist by however small a degree. If we grant this condition, which follows from the commitment to maximizing total utility, then we are faced with an obligation to bring as many happy people into the world as possible, however small the individual level of happiness of each person is. The most striking implication for intergenerational justice is that we act justly to the future when we make the size of future populations as big as they can be irrespective of how low the average utility of each member of those future generations might be. Whereas average utility suggests the imposition of particularly draconian population policies, total utility goes to the opposite extreme by encouraging population maximization. The full impact of this repugnant conclusion can be seen when we apply the total utility strategy to the choice between policies of depletion versus conservation. We need to be able to judge the relative utility or welfare of one population against another who would have lived if an alternative policy had been pursued. As long as the total utility of population a is greater than that of population b that might have existed as a result of a different policy choice, then we are justified in pursuing policy a over b. This can help us explain and justify some trade-offs between population size and level of utility such that we might prefer a policy that resulted in a larger population with a lower utility to a smaller population with a higher utility; for example, population a with n members each having a utility of 10 as opposed to population b with $2n$ members each having a utility of 8. But this approach becomes counterintuitive and repugnant when we consider the case of a third population of $10\,000n$ each having a utility of 0.01. In this latter case we face the repugnancy of the total utilitarian approach whereby as long as the population is large enough the utility of the individual members does not matter as long as it is above zero.

By rejecting the person-regarding aspect of justice arguments, utilitarianism can overcome the criticism that we only have obligations to assignable individuals (and therefore we cannot be said to have obligations to future generations) because of the nonidentity problem. They get around the problem only by exposing themselves to different problems resulting from their indifference to issues of distribution that are also at the heart of intergenerational justice arguments. Both forms of utilitarianism considered here address the issue of intergenerational justice by the artificial means of manipulating population size. This strategy either loads the dice in favor of existing generations as long as they are prepared to manipulate the size of future generations accordingly or to reduce our obligations to the simple duty to procreate as much as possible. Neither approach seems an adequate answer to the question of what if any obligations we have to future generations. The two main candidate theories for grounding claims of justice, contractualism, and utilitarianism have serious problems in making sense of the identity of future generations and the idea that we may have obligations to them. Does this mean that the skeptic is right and the idea of intergenerational justice is flawed?

The Prospects for Intergenerational Justice

The contemporary literature on intergenerational justice is largely focused on discussions of the paradoxical consequences of applying existing theories of justice to intergenerational problems. Does this mean that the skeptic is correct in arguing that the idea of relationships of justice between generations is incoherent? Two contemporary political philosophers, De-Shalit (1995) and Barry (in Dobson, 1998b) reject this skeptical position and suggest that there are ways we can overcome the skeptical position to make sense of intergenerational obligations. However, they do so from very different perspectives, De-Shalit is a communitarian, whereas Barry is a universalist egalitarian.

Transgenerational Community

De-Shalit begins with the challenge posed by the inadequacy of contractarianism and the nonidentity problem. Faced with the problem of asymmetry in the original position, Rawls introduces an additional motivation linking the generations to justify a just savings principle as a constraint on contemporary consumption. This additional motive that requires the participants to think as heads of families is supposed to model the motive to be concerned about our posterity. De-Shalit takes this natural motive and generalizes it across the idea of constitutive communities. Why should the family be the only repository of such a motive? His point is that it is not the particular institution that is the repository of this motive but the type of relationship. The contractarian and the nonidentity argument posit a sharp break between generations that creates an unbridgeable moral gap between persons. De-Shalit challenges this individualization by arguing that our identities are shaped and constituted by membership of communities.

Membership is itself obligation creating, in the same way that Rawls assumes that acting as head of families will provide the sufficient motive to assume obligations to the future. The motivation to be concerned about posterity is for De-Shalit a natural motivation and this is missed by the narrowly 'individualistic' approaches of contractarians and utilitarians. The task for the political philosopher is then not to construct the basis of the obligation to the future. We have this natural concern because our own identity and interests are tied up with the membership and existence of a certain type of community. The task is to expand the implications of that concern for posterity and the specific obligations that can be derived from it. Two important implications arise from De-Shalit's communitarian turn. First, he broadens the notion of those goods we have a duty to bequeath to posterity. Whereas much of the literature assumes merely that our obligations to the future concern material resources and the environment, De-Shalit's emphasis on constitutive communities entails that all those definitive aspects of such communities might be 'goods' that we have an obligation to preserve for posterity. Thus, we could have obligations to preserve languages and cultures or defining institutions such as constitutions and political rights. The second implication is that De-Shalit changes the focus of intergenerational justice from a universal to a particular one. We have obligations to our posterity and not future generations as such. The British people might have obligations to preserve their constitution for future generations, or the Quebequois might have an obligation to pass on their 'distinct society' to future Quebequois, but not to future Nigerians or for the good of future Japanese. For De-Shalit it is not assignable individuals that we need to worry about but only assignable groups. Obligations only extend as far into the future as it is reasonable to think a constitutive community will retain its identity.

One possible objection to De-Shalit's approach is that it makes group membership too important. If we only have obligations to our own posterity then we only have obligations to preserve the environment for our posterity. But this raises the counterintuition that it surely cannot be right that I have a duty to protect the environment for my own posterity but that if a policy of depletion falls not on my posterity but on another people then I have no obligation or responsibility. A second objection that there is not sufficient space to explore in full is how far De-Shalit's argument creates obligations to the past to sustain community supporting practices that define the relevant political community? We might find the idea of preserving the US constitution as an obligation that present-day Americans have to the founders partly comprehensible, although Thomas Jefferson might have found this puzzling. But would we find the idea of submission to or support of the Church of England as compelling an obligation although as an institution it has had an important role in constituting the British Polity. It is because of such 'perverse' consequences that many are reluctant to abandon moral universalism, or the idea that from a moral point of view spatial and temporal location are not ultimately significant.

Universalism Defended

The key intuition underlying the threshold universalism of Barry, McMahon, and Meyer is that place and time do not provide morally relevant bases on which to discriminate between the interests of those who fall under a principle. This assumption is morally basic, as such it must be defended indirectly by challenging the challenges to it and showing how it accords with our reflectively adjusted intuitions. We might, for example, show that it overcomes the narrow parochialism of De-Shalit's communitarianism. Alternatively, we might suggest that it is the intuition that underlies Rawls' additional motivation designed to supplement contractarianism. The universalist is also likely to reject the utilitarian variant because of the repugnant conclusions that follow from abandoning a person-respecting morality. A universalist might deny that we have an obligation to bring about maximal well-being if this results in the kinds of population policies that result in repugnant conclusions.

One simple way of avoiding this utilitarian paradox is to conceive of obligations of justice not in terms of promoting the good as maximal welfare but in terms of not harming the interests of the future generations. This is nicely illustrated by an example from Woodward (1986). An individual is denied a seat on an airplane flight on the basis of race/skin color. The plane subsequently crashes with the death of all on board. In such circumstances we would be disinclined to say that the act of discrimination reduced the individual's welfare or utility but we are likely to still consider the discrimination a harm to an interest of the individual.

This negative obligation to not harm the interests of others has implications for the redistribution of resources and benefits; it does not merely involve staying one's hand and refraining from reducing welfare. In this way we can argue that we have an obligation to give weight to the interests of future generations when we make irreversible consumption decisions. We ought not merely discard future people because they are in the future.

The major objection still facing this approach is the non-identity problem. We can only have obligations to assignable individuals but the identities of these individuals are contingent on the choices we currently make such that we cannot be said to be harming them. Referring to 'future generations' does not mark out the identity of those being harmed. One way to overcome this problem is to contest the idea that only assignable individuals can be harmed. Thus, it might make sense to say that our decisions about resource depletion can harm future generations relative to the absence of that policy even though the existence of particular individuals might be dependent upon that policy because there is a threshold below which any individual, actual or possible, should not fall. The threshold conception allows us to contest the idea implicit in the non-identity problem that we cannot be said to harm the interests of members of a future generation as their interests will be a function of the circumstances in which they find themselves. While it is certainly true that any complex account of universal transtemporal interests will be hard to conceive of, there are certain things that it can be argued will be in any subsequent individual's interest. It is clearly in no future individual's interest to live in a world in which potable water is made scarce by pollution, or in which ozone damage raises levels of carbon dioxide in the atmosphere and levels of harmful radiation. Future generations are also likely to place some value on their environment and biodiversity. How much each of these things

will matter is debatable, but that they will matter is uncontestable. Where this leaves the universalist is with the idea that we have obligations to take account of the 'general' interests of future generations not to be harmed in certain ways, whoever they happen to be and whatever else they happen to want. Thus, the burdens of intergenerational justice fall on contemporaries in the form of not harming those interests of future generations by over consumption, environmental depletion, and unsustainable development without permanent advances to any future generation.

The threshold conception of universalism can then be linked to other distributive criteria such as egalitarianism and prioritarianism of sufficientariansm to identify the most plausible account of intergenerational justice. An egalitarian view might set the threshold very high as it would require us to ensure that all future generations met a threshold equal to that of present populations. On the other hand, a sufficientarian account along the lines of Barry's argument might be said to provide a minimally humane concern for whoever comes after us.

As subsequent generations extend far into the future our common intuitions suggest that our obligations become weaker in terms of just savings and the transfer of resources hence the sufficientarian approach becomes more feasible. In the case of private individuals the motive to save for offspring is strong but weakens across many generations until we reach a stage where most are indifferent to distant posterity. But the universalist approach is able to accommodate this intuition because it transforms the debate from one of just-savings and the intergenerational transfer of wealth into a present-day concern for sustainable economic and political policies that do not worsen the position of those in the future. The idea of sustainable economic development has its own broad and complex literature but the idea of sustainability gives some content to how we might think about justice between generations. In this way the idea of justice between generations converges with the reasonable environmentalists' concern with respect for the environment as a common good. If we have obligations to future generations they are to respect the common resource that is the environment which we share. Where intergenerational justice differs from environmental ethics is that it regards the value of the environment as an aspect of human interests. This of course is not the only way we might regard it, but that is merely to recognize that even in the intergenerational case there is more to morality than justice.

Intergenerational Solidarity

Abstract

Intergenerational solidarity refers to any form of mutual support exchanged between generations. Focusing on the relationships between (adult) family members, Bengtson's paradigm of intergenerational solidarity distinguishes affectual, consensual, associational, structural, functional, and normative solidarity dimensions. The concept of intergenerational ambivalence additionally accounts for the coexistence of harmony and conflict in close relationships. In an attempt to understand individuals' motivation for intergenerational solidarity, several explanations are proposed and discussed in this article. Moreover, the theoretical framework introduced by Szydlik is outlined to account for the fact that intergenerational solidarity is principally a dyadic relation of individuals embedded in a family and in a social context. A discussion of the key findings on adult intergenerational solidarity is presented to illustrate patterns of (grand) parent–child exchanges.

Intergenerational Solidarity

Intergenerational solidarity refers to any form of mutual support that is exchanged between generations. While the cohort relationship is mainly a concern of social policy (i.e., the 'generational contract'), the focus of this article is on personal relations between family members of different generations, located in a system of ranked descent.

The present-day situation where members of a family belonging to different generations live many years of overlapping lives is unprecedented: in developed countries, most children have at least one parent alive until their sixth decade of life, and the grandparent–grandchild bond may hold up to four decades. Parallel with the verticalization of the age structure in the society, within the family age structure more people are occupying the top generational positions than in the past, and children are now more likely to have more grandparents than siblings or cousins (*see* Age Structure). What makes intergenerational relationships within the family so important is the fact that each person is involved in a parent–child relationship for most of their own lives. On becoming parents, individuals are likely to be involved in two types of parent–child relationships, being the child in one case and being the parent in the other.

Over the past two decades, the outstanding challenges posed by the ageing process with regard to intergenerational relationships in the family shifted the focus of research in this field more and more toward the relationships between elderly parents and adult children. In the later *empty-nest* life, the size of personal community networks tends to decrease because of the decline in resources, including income and health. A small number of geographically proximate members and long-time relationships dominate the social network of the elderly. For example, a recent study revealed that the average network size among Europeans aged 50 and above is between two and three members (Stoeckel and Litwin, 2013). 85% of them reported having a social network comprising solely (62%) or for the majority (23%) of family members. The partner and children are usually named as primary network members. However, generally having about the same age and lifestyle, the partner may fail to provide instrumental forms of help. Intergenerational relationships become, therefore, the basic opportunity for support.

Interest in the study of intergenerational solidarity has risen with the rapid aging of the population, although it dates back to the 1950s and 1960s when scholars were concerned with the weakening vertical family solidarity because of demographic trends, geographic mobility, and socio-cultural changes – the so-called *family-in-crisis hypothesis* (e.g., Sussman and Burchinal, 1962). Family studies of the time (e.g., Burgess, 1960; Parsons and Bales, 1955) emphasized the centrality of the nuclear family and the weakening of family bonds resulting in isolation of older family members. The sociologist Popenoe (1993) argued that the family has been cut back to its essentials: two generations (i.e., parents and children) and two functions (i.e., childbearing and provision of affection and companionship).

Given that "for a growing number of Europeans, living as a family today means living in longer, thinner, more often de-institutionalized (non-marital), non-co-resident families" (Hantrais, 2005, p. 4), adult intergenerational relationships within the family are shaped qualitatively and quantitatively different from the past. Yet, longstanding investigations of solidarity (*see* Family and Kinship, History of; Welfare State, History of) show that the family may have changed its structure or even its meaning, without losing its focal role of solidarity network for the family members.

This article first provides a discussion of the mostly used intergenerational solidarity paradigm; then it lays out the framework to understand family solidarity, by noting alternative theories that have been put forth by economists, sociologists, and demographers to explain the ties between generations. In addition, a discussion of the 'facts,' that is, what we know from empirical evidence on intergenerational solidarity, is included. A discussion of three-generation intergenerational solidarity concludes the article, accounting for the role of grandparents.

Solidarity, Conflict, and Ambivalence

The wide range of research on intergenerational solidarity from several fields (sociology, demography, anthropology, gerontology, and so forth) worked as an obstacle to the development of a uniform definition. Instead, many definitions were either circular or too narrow. However, "the focus on solidarity […],

whatever definition used, […] has the merit of documenting how intergenerational relations within families also maintain an important solidaristic role in increasingly individualized and welfare-state societies" (Saraceno, 2008, p. 10). The terminology of this article coincides primarily with the six domains of intergenerational solidarity which are key components of Bengtson's solidarity framework (Bengtson, 2001; Bengtson and Roberts, 1991), additionally touching on alternative schemes.

Bengtson's comprehensive scheme for describing sentiments, attitudes, values, behaviors, and structural arrangements in parent–child relationships distinguishes between affectual, consensual, associational, structural, functional, and normative solidarity. *Affectual* solidarity includes the sentiments and evaluations family members express about their relationship with other members; *consensual* solidarity refers to the agreement in opinions, values, and orientations between generations; *associational* solidarity is the type and frequency of contact between intergenerational family members; *structural* solidarity is the 'opportunity structure' for cross-generational interaction and reflects geographic proximity between family members; *functional* solidarity reflects the giving and receiving of both instrumental assets and services across generations; *normative* solidarity takes into account the expectations regarding filial and parental obligations, as well as norms about the importance of familistic values. Solidarity, along a number of dimensions, helps families function as cohesive units to fulfill member needs.

Although Bengtson's solidarity paradigm has been defined as the 'gold standard' for assessing intergenerational relationships (Silverstein et al., 2010, p. 1007), other investigators have developed broader or more detailed categories of informal helping behaviors between generations. Weiss (1974), for example, suggests a broad conception of six provisions in social relationships: attachment, social integration, opportunity for nurturance, reassurance of worth, a sense of reliable alliance, and obtaining guidance. First, individuals must experience a feeling of comfort. Next, the network should allow pooling and sharing of ideas and information. Third, individuals must have a sense of being needed by others. Fourth, others should tell or show individuals that they are important to them. Fifth, individuals have to be assured that their physical needs will be met or be supplemented significantly by others. The sixth provision is constituted of advice that individuals receive from teachers, parents, or others in authority during their life.

House (1981) adds precision to the definition of the resources that are exchanged in supportive transactions, distinguishing between *information* and advice, *appraisal support* (i.e., information relevant to self-evaluation, feedback, or help in decision making), *emotional concern*, including understanding and esteem available from others, and *instrumental aid* with needs (i.e., getting groceries, cooking, cleaning, or managing money). Informational, appraisal, and emotional support are frequently difficult to disaggregate. Krause (1987) further defines, within the instrumental dimension, the aid received (*tangible* assistance) and the support provided (*integration*).

Despite being mainly linked by mutual support, love, and happiness, family members are also likely to experience *conflicts* (Sprey, 1969). According to classical sociologists, the coexistence of closeness and conflict is inevitable in intimate relationships: parents and children may hold different interests and have power differentials. Continuing efforts to refine the solidarity paradigm, indeed, added 'conflict' as a seventh dimension to the family solidarity paradigm, generating what has come to be known as the *solidarity–conflict paradigm* (Bengtson et al., 1990).

However, assuming that affectual solidarity could capture closeness as well as conflict (being the antitheses of each other) would imply considering social interactions as being distributed over a continuum that ranges from positive to negative (i.e., from high solidarity and low conflict to low solidarity and high conflict). Yet, the relationship between parents and children may be characterized by high solidarity and high conflict or low solidarity and low conflict, both at the same time. The positive connotation carried by the term 'solidarity' should not hide the contradictions experienced in close social relationships.

The concept of intergenerational *ambivalence*, proposed initially by Lüscher and Pillemer (1998) and then expanded by Connidis and McMullin (2002), accounts for harmony and conflict in a multidimensional way. The ambivalence construct may complement the solidarity models and the conflict model, reflecting the emotional complexities of family life. Solidarity, conflict, and ambivalence are lenses through which to look at how family members deal with attachment and independence and how they negotiate them.

Especially in later life, tensions arise between the desire for autonomy and the likely need to become dependent on the adult children – to whom older parents were formerly providers (Silverstein et al., 2010). By applying the concept of ambivalence to family ties, researchers have moved away from the idea that family members maximize positive relationships and minimize negative interactions (van Gaalen and Dykstra, 2006).

Theory of Family Solidarity

The research on adult intergenerational solidarity has often been defined as 'atheoretical.' This vulnerability may be derived from the fact that family studies are mainly problem-driven and applied disciplines. A second criticism to the social science approach to intergenerational solidarity is its increasing 'microfication,' that is, giving particular attention to the psychological characteristics of the individuals.

Understanding intergenerational ties requires a theory about individuals' motivation for behavior. Indeed, several attempts have proposed explanations for intergenerational exchange. Moreover, a general theoretical framework has been outlined by Szydlik (2008) to account for the fact that intergenerational solidarity is principally a dyadic relation of individuals, embedded in a family and, beyond that, in a social context.

Starting from the individual level, the rational choice argument of the *exchange theory* regards intergenerational solidarity as a form of support with respective costs and rewards for the giver and for the receiver (i.e., the parent and the child in any of the two roles) (e.g., Emerson, 1976) (*see* Exchange: Social). Individuals will incur the costs of giving in anticipation of the (direct or delayed) rewards of receiving. In this perspective, intergenerational solidarity is based on self-interest.

In agreement with Szydlik's model (2008), the diverse conditional factors for solidarity can be classified into four groups: opportunity, need, family, and cultural–contextual structures. Costs and benefits of intergenerational solidarity are reflected in *opportunity* and *need structures* (see also Bordone, 2012 for a discussion). The first includes resources for solidarity, enabling or preventing it. For example, high levels of a child's educational attainment increase personal aspirations in the labor market (even at the cost of greater geographical distances from the parents). Education is, therefore, an opportunity that tends to prevent parent–child structural solidarity. Need structures stem for health problems or for emotional support as well as for necessity of financial nature. Solidarity is indeed *contingent* on the needs of both parents and children (Deutsch, 1975): for example, marital disruption suffered by the adult child might lead to an increase in the contact with the parent because of the child's need to get emotional comfort.

The *altruism theory* suggests that beneficence may also guide parent–child solidarity (Becker, 1974): parents and children care about each other and, therefore, provide each other various forms of support.

Within these broad perspectives there are several related models which help explain the complicated relationships observed among family members. It is plausible to assume that parents and children care about one an other and, therefore, make transfers as required to maintain or enhance the other's well-being, in concordance with altruism, exchange, and contingency hypotheses. Repeated exchanges within the family may derive from a compromise between emotional aspects and from what rationality dictates. However, the relation between parent and child also depends on *family structures*: family size, family composition, events that happened during the family life course as well as family roles and norms that reflect the entire history of socialization of the parent and the child. For example, the existence of more siblings (especially daughters) may lower the likelihood of providing functional solidarity to the parents.

At the micro-level, theoretical explanations have also been proposed concerning the tension between family members, mainly reflecting the competing pressures to maintain attachment and at the same time establish independence. Fingerman (2001), for example, refers to the competing needs of different generations as *developmental schisms*: while older parents may ask for more closeness, adult children struggle between multiple roles as partners, parents, children, and workers. Ambivalence in the relationship tends to emerge especially when the available resources do not offer many 'escape options,' that is, women, elderly, and poor will encounter more ambivalence than their privileged counterparts (for a detailed review, see Cooney and Dykstra, 2013).

Although the ideational approach widely known under the umbrella of the 'second demographic transition' (*see* Second Demographic Transition) emphasizes individual preferences in the decision-making process of individuals, intergenerational solidarity is also a feature of *cultural–contextual structures*, with roots laying far back in history. Moving upstream beyond the family and returning to a more Durkheimian orientation to social context, cultural–contextual structures should be taken into account by considering socioeconomic conditions, tax system, welfare system, labor and housing markets as well as social norms, legal duties, and policy arrangements, within which intergenerational solidarity develops. As such, they shape and reinforce intergenerational solidarity within a specific context, providing also a definition of dependence between generations.

Saraceno (2010), building on previous conceptual works, distinguishes three patterns in which legal norms and public provisions frame financial and caring obligations in families, both up and down family lines. *Familialism by default* exists when few publicly provided alternatives to family care and financial support are available. *Supported familialism* characterizes contexts where policies help families in maintaining their caring and financial responsibilities, usually through financial transfers. *De-familialization* applies when the individualization of social rights (e.g., minimum income provision, unemployment benefits, and care entitlement) limits family responsibilities and dependencies. This categorization, going beyond the public/private dichotomy of responsibilities, emphasizes that public family provisions may both motivate and lighten private family responsibilities.

The literature mainly refers to the crowding-in and crowding-out hypotheses when dealing with the offer of services from the family and the state. The state may indeed displace family services as in the case of family pensions taking over the provision of security in old age (*crowding-out*) or stimulate family support by relieving family members of time-consuming support and incentivizing them to provide voluntary services (*crowding-in*). State and family services may thus work in *complementarity*, dividing support activities according to the task-specific model (see, e.g., Motel-Klingebiel et al., 2005 for a discussion of these theses and an empirical testing).

Empirical Research: Key Findings

The intergenerational solidarity paradigm has been validated with data from many countries around the world. Although the discipline-specific language and methodology make it difficult to draw broad conclusions, empirical patterns found in previous work are discussed here with a focus on Bengtson's intergenerational solidarity framework.

Affectual and Consensual Solidarity

Emotional closeness and consensus of opinions between parents and adult offspring reflect affinity between the generations. The affective bond is central to the parent–child relationships in order to engage in solidarity exchange. Emotional ties with offspring may be of extremely high value for aging parents facing the loss of significant social ties (e.g., spouse and siblings) due to death, and the vanishing of social roles, for example, due to retirement. Indeed, children are identified by most aged parents as close confidants (Connidis and Davies, 1992). This is especially the case for mothers, who are less likely than fathers to name their respective partner as their preferred confidant. Although parent–child relationships tend to be judged positively, also from the perspective of adult offspring, they are reported of higher quality with respect to mothers than to fathers (Silverstein et al., 2010; van Gaalen and Dykstra, 2006). Moreover, adult children report less closeness

to the parents, compared to their parents' ratings of their relationship (Fingerman, 2001).

In the 1960s and 1970s, research began to give much more attention to the 'generation gap' in attitudes – i.e., the lack of consensus in values and opinions between generations – as fostered by the socio-political changes of the time. By definition, consensus is a relational variable for which an individual can provide information about the extent to which he or she perceives agreement or disagreement with another individual. Although this clearly implies that reports from a single family member are inadequate, most studies concerned with the similarity of views between generations use 'generational-level' analysis. Accordingly, self-reports from one generation have been compared with those from another. Alternatively, maintaining the family as the unit of analysis, measures of agreement provide answers to the question regarding the extent to which reports from parents and their children are similar or different.

Pruchno et al. (1994) showed that consensus between mothers and children, and between fathers and children may be best represented as two constructs (mother–child consensus and father–child consensus) rather than as one construct (i.e., parent–child consensus). Moreover, contrasting reports from mothers or fathers and their children indicate significant differences in the reports: mothers reported higher levels of agreement than did their children on how money is spent, religious matters, friends, making major decisions, and dating, while fathers reported higher levels of agreement than did their children on religious matters and dating. Children reported higher levels of agreement than did their parents on aims and goals, household tasks, career decisions, and education.

Associational and Structural Solidarity

Frequency of contact and geographic proximity between the parent and the child reflect the opportunity structure of the relationship. The associational dimension of solidarity is highly correlated with other forms of solidarity: parents and children who are more often in contact are more aware of each other's needs than those with lower frequency of contact and react to them by providing affectual solidarity and instrumental help. In particular, frequent in-person visits strongly predict functional solidarity exchange (van Gaalen and Dykstra, 2006). Both studies on American and on European data reported high levels of contact between parents and children: the majority of older parents have weekly contact with at least one child (e.g., Hank, 2007; Lawton et al., 1994). The observed decline in weekly visits to the parents in some countries may be justified by a possible counterbalance between individualistic aspirations and other compositional changes. Consistently, literature has found that parent–child contact is higher when children have own children and lower when parents are divorced (especially with the father). Greater geographical distance also predicts lower frequency of contact, not only face-to-face. The use of new technologies that facilitate communication (e.g., Internet) may increase the level of parent–child contact even when living geographically far from each other. Cross-national variation still exists within Europe, with Mediterranean countries reporting higher levels of contact than Northern European countries (e.g., Bordone, 2009; Hank, 2007).

The dimension of distance, in addition to frequency of contact, is important because close relatives are necessary to provide some other forms of solidarity. Geographical distance, however, may not be exogenous to intergenerational associational and functional solidarity: family members might choose to move closer to one another (or together) because support is required by one or both generations. Coresidence can facilitate intergenerational solidarity in numerous dimensions (e.g., emotional support and instrumental help) and can be an alternative for financial transfers both downward and upward. The person in need is usually most likely to move, and this is also why having a spouse reduces the likelihood that elderly parents reside with one of their children; while a child's divorce is a driving factor for moving in with the parents (see Cooney and Dykstra, 2013 for a more detailed discussion of related empirical evidence). Not only coresidence, but also geographical proximity may benefit both parties: living near each other allows for intergenerational solidarity as well as independence. The literature shows that fertility decisions are positively affected by having local parents, especially in countries where public childcare is limited. Moreover, having parents nearby who can provide grandparental childcare may help women balance work and family duties.

Functional Solidarity

Upward and downward exchange in terms of financial and time transfers, including all kinds of care-giving activities and instrumental support, are interrelated dimensions: assistance provided through one form of solidarity may either substitute or complement some other type. A particular form of downward time assistance is grandparenting, which we discuss subsequently. The type, direction, and amount of functional solidarity exchanged depend on three aspects, in addition to geographical distance. First, the needs and opportunities of both givers and receivers: for example, higher-income family members may substitute time-related transfers with financial transfers; second, welfare regimes: in countries where pension levels are high, the oldest old are less likely to receive money from their children and more likely to help them financially; third, the position of individuals in the life course: the oldest old tend to be net recipients and the pivot generation is more likely to engage in giving (Attias-Donfut et al., 2005).

In general, cash gifts tend to flow to the younger generations, even after children are grown and are living on their own. Using data from the Survey of Health, Ageing and Retirement in Europe (SHARE website http://www.share-project.org/), Albertini et al. (2007) reported that 21% of older parents noted providing monetary help to an adult child in the last year, with only 3% receiving such help. As shown by Attias-Donfut et al. (2005), rates of making financial transfers are higher for parents in a couple than for singles. In contrast to inter vivos transfers, often targeted to the more needy children or grandchildren, bequests are mostly divided equally among children.

Parents are also much more likely to provide time assistance (over a wide spectrum of tasks) to their children (especially to divorced or never married daughters with children) than to receive it, at least until late in life when their growing needs for help change this balance. However, functional solidarity,

understood in its informal care component (i.e., personal care, practical household help, and help with paperwork), is usually reported upward, although in modest levels in most families. A substantial minority of older American parents typically have received some routine assistance from their adult children (e.g., Davey and Eggebeen, 1998). In Europe, 16% of elders report to be recipients of instrumental support from their offspring (Albertini et al., 2007). Bonsang (2009) showed that, on average, the 65 year olds and older with at least one child in Europe receive 5.6 h of informal care per month from children not living with them. However, evidence consistently points to a significantly higher likelihood of older parents getting help from their children when needs arise.

Country differences exist in the rates and amounts of transfers; however, empirical studies in the field did not easily identify generalizable results to group countries together based on financial and time-assistance patterns (Attias-Donfut et al., 2005). The consequences of these private transfers are important for both individuals and social policies concerning the redistribution of wealth in the society (Attias-Donfut et al., 2005).

Normative Solidarity

The belief about family members' responsibilities to care for and support one another is a core aspect in theories about the family because it largely helps explaining associational and functional solidarity between parents and children. Research linking family obligation to solidarity behavior has produced inconsistent findings, often because norms for intergenerational solidarity are inadequately conceptualized and measured. Several cross-sectional investigations find that providers and receivers of support tend to report higher filial responsibility compared to those who are not involved in intergenerational exchanges. Other research finds no association between the endorsement of filial responsibility and actual support (see Cooney and Dykstra, 2013 for a deeper review of these studies).

Evidence from longitudinal studies on the effect of normative solidarity on support behavior, although mixed, tends mostly to suggest that filial obligations have a stronger motivational component for sons than for daughters. As Cooney and Dykstra (2013, p. 360) suggest: "females appear less sensitive to social prescriptions, perhaps because they take support provision for granted." Although strong feelings of family responsibility may predispose individuals to be supportive, whether assistance actually materializes depends on the specific context of need.

Inconsistencies across countries have also been found with norms being more powerful determinants of behaviors in countries with limited public support systems (see Cooney and Dykstra, 2013 for a detailed review).

Compared to the evidence on filial obligations to aging parents, less is known about how people view the responsibilities of parents in middle and late life toward adult children as studies on parental responsibility usually refer to parents' responsibility for young children. The Survey of Health, Ageing and Retirement in Europe (see SHARE website http://www.share-project.org/ for a detailed list of references), though, asks about the opinion on whether grandparents' duty is to help grandchildren's parents in looking after grandchildren or whether grandparents' duty is to contribute toward the economic security of grandchildren and their families. Descriptive evidence on these items shows that Mediterranean countries appear to be characterized by stronger family values than Central and Northern European countries.

Mutual support between generations is not always voluntary, but it is sometimes based on normative pressure or legal duties. An example is economic assistance, legally regulated, by parents to children until a certain age and later on in life by adult children to their parents (for further data on this issue, refer to the social policy indicators available on the Multilinks project website http://www.multilinks-project.eu/). National and comparative survey data, as well as qualitative studies on intergenerational support, show that the higher the space of familialism by default, and to some degree also of supported familialism, the higher the impact of gender and social class differences among the potential family carers (see Saraceno, 2010 for a review).

Ambivalence

Individuals tend to identify some problems with their adult children and with their parents, often related to communication and lifestyle. However, the majority of adult children define the ties to their parents as solely close, one-third define them as ambivalent, and only about 6% experience the relationship with the parents as solely problematic (Fingerman et al., 2004). The coexistence of high solidarity and high conflict is not a general state, and it is mainly found among young adults (van Gaalen and Dykstra, 2006).

Evidence (see Cooney and Dykstra, 2013) consistently shows that levels of ambivalence not only vary with geographical proximity (i.e., closer parent–child proximity is associated with more mixed feelings in their relationship), but also depend on the gender and marital status of the parent (ambivalent relationships are reported more with fathers than with mothers, and with currently unmarried parents compared to partnered). Empirical results also support the idea that ambivalence may result from issues of balancing attachment and independence. Parents' health is a significant predictor of ambivalence in reporting from both parents (Pillemer et al., 2007) and children (van Gaalen and Dykstra, 2006). Parents report ambivalence in their parent–child relationship also when their adult children have health problems and, especially mothers, when they have issues with the law or have chemical dependency (Pillemer et al., 2007).

Literature also shows that parents and children usually express their feelings openly. In turn, unresolved parent–child tensions may detract from affectual solidarity.

Which generation is reporting their feelings may also matter: despite providing more assistance to their offspring than receiving, mothers tend to report lower relational ambivalence than adult children. Different relational expectations may explain this evidence.

The Macro-Level

The availability of cross-country comparable surveys investigating intergenerational solidarity in its various dimensions has incentivized the proliferation of studies examining

determinants of intergenerational solidarity variation among different individuals as well as among a larger number of countries.

The first type of studies, where the micro (individual) level was the focus of the analysis, accounted for context by including country indicators to the regression models. Several comparative studies showed that both needs and opportunities of the recipients and givers exert a comparable influence on the exchange of support in different countries. However, the diversity of intergenerational relationships from country to country remains significant within Europe, highlighting a North–South divide. Therefore, a second type of studies gave attention to cultural–contextual and policy explanations at the macro-level in multilevel analysis. Although the most common discussion at the macro-level is on the distinction between weak versus strong family ties, likely linked to specific welfare systems, the nonstrict correspondence required further investigations. Political economy focused studies took into account the social context of elderly people centering around help and care from a welfare production point of view (e.g., Brandt et al., 2009). Some explorative works on the societal level have shed light on the importance of social norms in relation to family solidarity (e.g., Bordone, 2012).

Theoretical and empirical works on family solidarity tend to assume that, as the family is a reliable and nonjudgmental institution that crosses generations, it has both a direct and a mediated effect on health conditions through support between its members. Usually this strand of research shared the assumption that family solidarity (positively) influences physical and mental health status (Berkman et al., 2000). Several conceptual causal frameworks have been proposed to highlight the upstream and downstream factors that are likely to explain a causal link between solidarity and health outcomes, but this is another (although related) story, which is not discussed here.

A Three-Generation Perspective: The Role of Grandparents

The new opportunity role of grandparents has enlarged studies of intergenerational solidarity to three family generations: grandparents, parents, and (grand)children. Although in most developed countries there has been a decline in multigenerational households, grandparents still play an active and supportive role within the family, especially by taking care of grandchildren. Indeed, the proportion of elderly giving functional solidarity to offspring increases significantly when childcare is included in support measures. Taking care of grandchildren is a common activity among grandparents in Western societies, especially among women: in the USA, 50% of grandparents provide some type of childcare; similar percentages of grandfathers in Europe say they provide regular or occasional care to their grandchildren and even more grandmothers (58%) are involved in childcare (see Glaser et al., 2010 for a review).

As grandparental childcare is traditionally considered an altruistic act, research on this intergenerational exchange has focused on its effects on younger generations. By helping their children (especially daughters) with looking after grandchildren, the (unpaid) grandparents are also likely to produce welfare benefits, especially when the services offered by the market are costly and public provision of care is scarce. In some countries, the important role of grandparents as providers of childcare has already been officially recognized: in the UK, for example, grandparents who give up paid work to provide childcare can claim credits that allow them to qualify for a basic state pension (Glaser et al., 2010).

Grandparental childcare can be seen as both a downward and an upward transfer: on the one side, grandparents invest time and resources in their grandchildren; while on the other side, grandchildren are an important (emotional) resource for grandparents. Economic models have indeed hypothesized that inter vivos transfers from grandparents to grandchildren might also have an egoistic component that can help to explain why older generations transfer resources to younger generations. Downward monetary and time transfers may be motivated by the anticipation of future need, and the hope that the younger generations will be more altruistic toward their parents or grandparents in return. According to this strand of literature, grandparental childcare could be considered an investment that is expected to pay off in the future.

Focus has also been laid to consensual solidarity between grandparents and grandchildren. Giarrusso et al. (2001) found evidence for a strong relationship between grandparents and their adult grandchildren: "longer life expectancy appears to result in long-term loving relationships" (p. 473).

In sum, adult intergenerational relationships between (grand)parents and children remain a relevant aspect of aging and family studies. Reductions in mortality and decreases in fertility in most parts of the world will also reshape intergenerational solidarity patterns in economies currently in transition and in developing countries, affecting large numbers of the global population. Increasing diversity in family forms and norms will also continue to impact on the variability in family bonds, raising new research questions and requiring new theoretical explanations.

Intergroup Relations

Jorge Vala and Rui Costa-Lopes, Institute of Social Sciences – University of Lisbon, Lisboa, Portugal

Abstract

This article provides a succinct description of the most significant socio-psychological research and theoretical breakthroughs in the area of intergroup relations. The first section focuses on contemporary socio-cognitive theories that highlight the role played by social categorization in intergroup relations since these theories and their links with motivation and emotion massively inspire current research in this domain. The subsequent section focuses on the perspectives on intergroup relations that have emerged in the past two decades and that have reinvigorated the study of collective beliefs, ideologies, and social norms as important organizers of group behavior, specifically through the legitimation of biased intergroup attitudes.

From a socio-psychological perspective, intergroup relations are "the systematic study of relations between individuals as they are affected by group membership" (Stephan, 1985, p. 599).

The social psychology of intergroup relations has been structured in accordance with three main problems: (1) what kind of factors are responsible for the fact that our collective and individual behavior is largely determined by our membership of and identification with social groups; (2) why do intergroup relations involve a significant degree of negative aspects such as discrimination, negative attitudes, and prejudice; and (3) how can these negative aspects be reduced and intergroup relations improved? This article mainly analyzes the first two issues without overlooking the third issue.

In a historical and comprehensive piece of analysis, John Duckitt (1992) offers a highly stimulating taxonomy of the theoretical factors underlying racial prejudice. This taxonomy can also help us to understand the various socio-psychological approaches to intergroup relations and their relation to historical milestones. Accordingly, we provide a succinct description of the main phases of research on intergroup relations, starting with the period following one of the important of such milestones: the Second World War. Indeed, it was after this major conflict that research in this domain flourished, stimulated by the need to understand Nazi racial ideology and the Holocaust. During the Second World War and for a decade after it ended, negative intergroup relations were mainly conceived as an expression of a pathological need and theoretical and empirical approaches to the subject stressed personality factors and individual differences. The prototypal and most influential study carried out within this framework was Theodor Adorno and his collaborators' analysis of *Authoritarian Personality* syndrome in the 1950s.

Still in the 1950s, the focus moved from personality to social norms and sociocultural and socio-structural factors. Two works can be singled out as good examples of the foundations of this analytical perspective. First, the famous 'Robbers' Cave Experiments' carried out by Muzafer Sherif and his colleagues. These experiments highlighted the structural role played by social norms, group interests, and functional relations between groups – namely competition versus cooperation – with regard to the quality of intergroup relations. A second good example of the perspectives that emerged in this period is Tom Pettigrew's (1959) research on the relevance of socio-institutional factors to the quality of intergroup relations. Pettigrew empirically showed that, despite the importance of personality factors, sociocultural and institutional dynamics were crucial in explaining the differences between anti-black attitudes in the Southern US versus the North and between the United States and South Africa.

A new analytical shift in the analysis of intergroup relations occurred in the 1970s with the flourishing of the cognitive perspective in all domains of social psychology. Following the seminal hypotheses proposed by Gordon Allport (in his classical work *The Nature of Prejudice*) concerning the role of social categorization in the dynamics of intergroup relations, two influential works emerged. First, Doise (1976) proposed the categorical-differentiation model, which suggested that the differentiation between in-groups and out-groups generates corresponding differentiations at the evaluative and behavioral levels. Secondly, Tajfel and Turner (1979) developed Social Identity Theory (SIT), in which social comparison and social categorization constitute anchoring processes despite the fact that motivation (to achieve a positive social identity) is the core psychological mechanism behind this theory. SIT continues to inform the debate on intergroup relations based on the assumption that social categorization per se (the in-group/out-group categorization) is a sufficient condition to create in-group bias, that is, to glorify in-groups relatively to out-groups.

Besides the contribution made by the socio-cognitive approach, since the 1980s, several theories approached intergroup relations through the analysis of social norms, collective beliefs, ideologies, and implicit theories about human beings (Crandall and Eshleman, 2003; Jost and Banaji, 1994; Katz and Hass, 1988; Leyens et al., 2000; Sidanius and Pratto, 1999).

Although this encyclopedia article is framed by the taxonomic and historical perspective presented above, it addresses only the last two approaches. Thus, the first section of this article focuses on contemporary socio-cognitive theories that highlight the role played by social categorization in intergroup relations since these theories and their links to motivation and emotion massively inspire current research in this domain. The second section of this article is devoted to perspectives on intergroup relations that have emerged in the last two decades and that have reinvigorated the study of ideologies and social norms as important organizers of group behavior, specifically through the legitimation of biased intergroup attitudes. These more recent perspectives provide systematic approaches about

the content of the formal processes identified in earlier socio-cognitive approaches.

Social Categorization and Intergroup Relations

William G. Sumner carried out pioneering research into intergroup relations, introducing terms such as we-group (later transformed into in-group – the group to which we belong) and others-group (later transformed into out-group – the group to which we do not belong) and identifying ethnocentrism as a worldview in which people use the in-group as the reference by which to scale and assess the value of things. Sumner was also the first author to advance the idea that affiliation to the in-group was associated with an ongoing conflict toward the out-group. (This view was later challenged by Brewer (1999), who posited the independent existence of in-group love and out-group hate.) Several decades later, data from field studies (LeVine and Campbell, 1972) provided evidence of this tendency to differentiate social environments in accordance with in-group-out-group distinctions and to value in-group characteristics over those of relevant out-groups.

Around the same period, theoretical frameworks were being developed in the social psychology of intergroup relations in order to integrate the impact of social categorization following the paradigmatic cognitive shift mentioned above. Doise (1976) proposed the model of categorical differentiation. This model is based on the structural role played by social categorization in intergroup relations and proposes that categorical differentiation between in-groups and out-groups generates corresponding differentiations at the evaluative and behavioral levels. Simultaneously and more significantly, a work that is arguably one of the most influential theories of intergroup behavior – SIT – was being developed in response to intriguing data emerging from earlier laboratory research. In the classical minimal group studies, Tajfel and colleagues had conducted empirical research that sought to determine the minimal conditions for the emergence of in-group bias. They challenged the idea – derived from the 'Robbers' Cave Experiments' – that a conflict of group interests is a precondition for the emergence of discrimination and bias between two groups. Instead, Tajfel and colleagues believed that competition was a sufficient but not necessary condition for the emergence of such phenomena. Thus, a minimal group paradigm was developed in which the participants used matrices to allocate resources without interacting with fellow group-members and without considering personal gain. The results clearly showed that, even though a general effort to act fairly was made, the participants revealed a significant tendency to award more points to in-group than to out-group members, providing the first empirical support for the idea that the mere existence of a distinction between an in-group and an out-group could, within a specific set of circumstances, constitute the minimal condition for the emergence of in-group bias. These results were largely replicated in several independent studies (but see Jaap Rabbie and colleagues' stance on this matter).

To explain these results, Tajfel and Turner (1979) developed SIT. Unifying structural, motivational, and cognitive dynamics, this theory postulates that in-group bias (which may be elicited by categorization but is contingent on structural factors such as groups' relative status, perceptions of status legitimacy and stability, and group permeability) is a motivational response to attain a positive self-image through social comparisons (see Vignoles et al., 2000). As such, in-group bias emerges to make the in-group positively distinctive from the out-group in ways that are relevant to (and valued by) the in-group. However, according to this theory, in-group bias is just one of a set of possible strategies that an individual may use to achieve positive distinctiveness. SIT was criticized for several reasons, such as its failure to acknowledge that self-esteem was not consistently associated with in-group bias or that in-group bias does not occur for negative aspects. However, not only have most of these criticisms been debunked as misunderstandings, this theory has also influenced a highly significant amount of social psychological research on intergroup relations. After the death of H. Tajfel in 1982, Turner and colleagues sought to elaborate on the cognitive elements of SIT, leading to the creation of *Self-Categorization Theory* (SCT) (Turner et al., 1987). While SIT asserted the importance of the categorization process by invoking the value for the individual of achieving a positive distinctiveness, SCT focused on the perceptual and cognitive determinants of categorization and elaborated on the consequences of the individual perceiving him/herself as a group member for both intragroup processes and intergroup behavior.

Several other phenomena that build on the process of social categorization have been identified within social psychology and provide additional and interesting insights into the functioning of intergroup relations. One important example that combines SIT and SCT to approach both intra- and intergroup dynamics is the *black sheep effect*. – that is, when deviant in-group members are judged more negatively than comparable out-group members (Marques and Páez, 1994). The *out-group homogeneity effect* also provides an important extension of the consequences of social categorization. It consists of a tendency to see out-group members as more similar to each other than to in-group members, even though this effect is more pronounced for dominant than for dominated groups (e.g., Lorenzi-Cioldi, 1993). It is significant that this perception has been found to be associated with more negative intergroup perceptions in several studies. Another process that builds on a cognitive mechanism that is related to social categorization and is also associated with negative intergroup perceptions (namely, stereotypes) is *illusory correlation*, which can include the perception of a relationship between a particular category of membership and a particular feature when no such relationship exists (Hamilton and Sherman, 1989).

The research mentioned above consolidated the idea that categorization is the process that should be addressed in order to resolve intergroup conflict or to promote harmonious intergroup relations (see Park and Judd, 2005; for an interesting discussion on the subject). As a result, research on intergroup relations that centered on the attenuation of intergroup conflict, which began in the 1950s with the *Contact Hypothesis* with Gordon Allport (see Pettigrew and Tropp, 2006), became more focused in the 1980s on the development of theoretical models that operate (real or perceptual) transformations in group categorization.

Decategorization

Brewer and Miller (1984) developed the Decategorization Model, which built upon Allport's (1954) Contact Hypothesis. Decategorization focuses on one of Allport's conditions for successful intergroup contact: in order for contact to lead to harmonious intergroup relations, the contact interaction cannot be 'category based.' According to this model, if people do not use social categories as a mental framework by which to judge others, they will be able to recognize the uniqueness and positive characteristics of each person – in this case, the out-group member. In fact, these 'personalized' interactions are assumed to result in the disconfirmation of negative stereotypes about the out-group. A major critique of this approach relates to the supposed difficulty of making positive generalizations about other members of the same out-group precisely because individuals are not thinking within this intergroup framework.

Recategorization

In 1993, Gaertner, Dovidio and colleagues developed a different strategy within the Common In-group Identity Model (CIIM). Like Brewer and Miller (1984), the authors of this model also considered it important to reduce the salience of in-group–out-group category distinctions, albeit by using a different process. According to this model, this reduction could be achieved by transforming the cognitive representation involving the two groups (recategorization). In this case, positive intergroup attitudes would follow from the perception of a superordinate category that includes both groups (see Guerra et al., 2010). However, this strategy runs into the same problem as that associated with the decategorization strategy: ignoring the in-group–out-group categorization results in diminished generalization. Another problem with this strategy is that it seeks to eliminate group memberships that might be significant and important to individuals and which they might prefer not to abandon. One final problem with this strategy concerns the fact that the superordinate category that results from this recategorization creates an opportunity for the dominant group to assert its superiority by claiming a higher degree of prototipicality in relation to that category (Mummendey and Wenzel, 1999).

Mutual Intergroup Differentiation

While the previous two models share the assumption about the need to reduce category differentiations, the strategy proposed by Hewstone and Brown (1986) within the Mutual Intergroup Differentiation Model (MIDM) takes a different approach. Hewstone and Brown suggest that cooperative interactions between two groups should be promoted without degrading in-group–out-group categorizations. Indeed, influenced by the idea of the (positive) effects of positive goal interdependence (cooperation) depicted within Realistic Conflict Theory, these authors suggest that harmonious intergroup relations derive from cooperative interactions in which the in-group and out-group have different but complementary tasks, competencies or resources (see also Deschamps and Brown, 1983).

Dual Identity

More recently, Gaertner and Dovidio (2000) developed a refined version of the CIIM by presenting a different strategy that combines the central tenets of CIIM and MIDM, invoking an inclusive category that preserves the subgroup identities. The authors assume that this dual representation is possible since individuals can conceive of two groups (e.g., Portuguese vs Dutch) as distinct entities within a more inclusive category (i.e., European). Although this strategy partially responds to some of the problems identified with the recategorization strategy, in this approach groups that are not included in this dual categorization are targeted with even stronger negative attitudes.

A recurrent critique of the categorization approach to intergroup relations concerns the way that it neglects the affective component of intergroup attitudes. As Park and Judd (2005) put it, the intention was probably to 'add it back in' after the cognitive dynamics had been unraveled. However, aside from some notable exceptions (Mackie et al., 2000), this cognitive approach to intergroup relations continues to be unable to bring affective aspects back into the picture. If one critical aspect of the role of categorization has been its failure to establish links with emotional aspects, another issue that has appeared more recently is related to ideologies of intergroup relations. A very recent exception in this regard is the work carried out by Costa-Lopes et al. (2014), which focused on the relationship between categorization salience and bias. In this case, the discussion is not so much about whether merely dividing individuals into two groups creates in-group bias, but whether drawing attention to such a distinction per se affects intergroup attitudes. In fact, this has become the new focus of research within the general domain of categorization and intergroup relations. Following Park and Judd's (2005) idea that our understanding of this relationship could be enhanced by considering the role played by ideologies such as multiculturalism, Costa-Lopes and colleagues developed research that shows that categorization salience only leads to in-group bias when a multicultural ideology is not made salient. Although still incipient, this research constitutes an example of how intergroup-relations research has more recently been characterized by emerging perspectives that reconsider the study of ideologies and social norms as important organizers of group behavior.

Fundamental Collective Beliefs, Ideologies, and Intergroup Relations

As stated above, the central role played by social cognition in intergroup relations should not be linked only to affect, emotions, and motivation but also to fundamental beliefs and ideologies that regulate social life. It was in this vein that Henri Tajfel (1984) associated his theory of social identity and intergroup relations with social change, perceptions of fairness, and legitimacy. He recommended studying the power of social myths and conceptions of social justice in intergroup relations. This analytical perspective was followed by the approaches described below. We begin this section by presenting some of the main theories about legitimacy and intergroup relations, after which we present some theories that link justice concerns to

intergroup relations. Finally, we present some implicit theories about human nature and their impact on intergroup relations.

Intergroup Relations and Legitimacy

Social Identity Theory

The importance of legitimacy processes attributed within SIT was initially considered by Turner and Brown (1978). These authors manipulated group status (high vs low), legitimacy (legitimate vs illegitimate), and stability (stable vs unstable) of this status. The results showed that perceiving relative group status as legitimate caused the high-status group to favor the in-group and the low-status group to favor the out-group. Moreover, in the condition where group status was seen as unstable and illegitimate, members of the high-status group diminished the degree of in-group favoritism and the low-status group revealed in-group favoritism. It was only in the latter condition that the low-status group exhibited some form of in-group bias. Indeed, the issue of legitimacy is a fundamental concern in democratic societies and legitimation is a core process in intergroup relations. Social Dominance Theory (SDT; Sidanius and Pratto, 1999) and System Justification Theory (Jost and Banaji, 1994) have a prominent place among the theories that have contributed to understanding the psychological mechanisms underlying legitimation.

Social Dominance Theory

Sidanius and Pratto (1999) proposed that societies evolved as 'group-based social hierarchies' and that these social hierarchies are served by legitimizing 'social myths.' The degree of endorsement granted to group-based hierarchies constitutes the level of social-dominance orientation (SDO) and the higher this orientation, the higher the level of support for social inequalities and discrimination against socially dominated groups. Several social myths enhance (hierarchy-enhancing myths) or weaken (hierarchy-attenuating myths) the legitimacy of social hierarchies, and the prominence of a group-based hierarchy within a given society is the result of the relative salience given to these two kinds of myths. According to SDT, meritocracy is an example of a 'hierarchy-enhancing' myth that produces an illusion of justice, serves the status quo, and legitimizes established social hierarchies. In fact, Katz and Hass (1988) used unobtrusive measures to experimentally demonstrate that the salience of egalitarian values decreases prejudice whereas the salience of meritocracy increases it. However, as Son Hing and colleagues demonstrated (Son Hing et al., 2011), it is important to make a critical distinction between meritocracy as a descriptive versus a prescriptive belief. Meritocratic principles can function as a hierarchy-legitimizing factor only among those who believe that meritocracy reflects current outcome distributions in society, that is, when meritocracy is a descriptive belief.

System Justification Theory

The justification of intergroup power relations and status inequalities was also construed within an ideological approach by System Justification Theory (e.g., Jost and Banaji, 1994). The goal of this theory is to analyze the conditions that facilitate the fact that most individuals adapt, defend, and justify the status quo and tolerate social injustice and intergroup inequalities. This theory proposes that, through the process of socialization, individuals acquire a motive for justifying the status quo even when it perpetuates their own disadvantaged position. People would engage in system justification because this serves as a *palliative function* as it reduces anxiety, discomfort, and uncertainty for both advantaged and disadvantaged individuals. In this context, the theory offers an ideological explanation both for out-group favoritism, which is frequently found in both correlational and experimental research among dominated or low-status groups, and for the in-group favoritism expressed by high-status groups, thereby indicating that both such positions indicate support for the system. Inspired by cognitive dissonance theory, this theory hypothesized that disadvantaged groups will show stronger support for the social system than members of advantaged groups because the former have a stronger need to reduce ideological dissonance through system justification. However, the robustness of this effect has not been demonstrated. Be that as it may, this constitutes a mere part of the story and the question about why individuals and groups strive for social change remains pertinent. Competitive interests, identity needs, and perceived injustice constitute factors that trigger collective action and promote social change.

The Justice Motive

Perceived Justice and Relative Group Deprivation

In the context of democratic societies, legitimation is a multilevel process and relative deprivation theories offer a framework by which to understand the origins of group status (il)legitimacy and some of the conditions for intergroup antagonism, that is, the feeling of injustice generated by the perception of relative deprivation. In this vein, Walker and Pettigrew (1984) revised the concept of relative deprivation in the context of intergroup relations and linked it to SIT (see also Mummendey and Wenzel, 1999, Kawakami and Dion, 1995). Correlational research has demonstrated that feelings of illegitimacy, negative intergroup attitudes, and a predisposition to engage in social action were generated by fraternal deprivation deriving from intergroup comparisons but not by egoistic or individual deprivation deriving from interpersonal comparisons. Significantly, some theoretical approaches to justice perceptions have proposed that judgments of justice and relative deprivation are based not only on the favorability of expected outcomes but also on the perception of respect for fair procedures (e.g., Tyler and Blader, 2003). If the feeling of group deprivation could generate judgments of illegitimacy, then the feeling of group gratification could produce feelings of legitimacy in relation to group-status inequality. Guimond and Dambrun (2002) hypothesized and experimentally demonstrated that when people are assigned to a condition of relative gratification they stereotype more and evaluate minorities such as immigrants more negatively. A possible explanation for this result could be that relative gratification facilitates a motivation to justify group advantages and social inequalities. Consequently, people in that condition express a greater degree of stereotyping and more negative evaluations of underprivileged minorities. This explanation of the consequences of group gratification proposed by Guimond is inspired by Social Dominance Theory and System Justification Theory, described above.

Belief in a Just World and Intergroup Relations

The role played by people's ideas about what is fair and just in the organization of individual and collective behaviors and attitudes constitutes an important legacy of the research in social psychology. Central to the legacy of the role played by justice concerns in our societal life is the Just World Theory proposed by Lerner (1980). According to this theory, individuals believe that the world is just in the sense that, at least implicitly, people get what they deserve and deserve what they get. In this sense, injustice, particularly the suffering of innocent victims, constitutes a threat to the belief in a just world, leading individuals to engage in different strategies to reestablish this belief, such as devaluing the victims' suffering or implicitly considering that they deserve to suffer. This theory was developed in order to understand judgments of fairness at the individual or interpersonal levels. The theory was, however, extended to intergroup relations by Correia et al. (2007). The authors analyzed the hypothesis that injustices that occur to innocent victims only threaten our belief in a just world if the victims belong to 'our world' (our in-groups) but not when victims are members of out-groups. This hypothesis was experimentally examined and confirmed using unobtrusive/implicit measures; in other words, the suffering of an out-group victim was not perceived as unjust. Quoting Tajfel (1984, p. 698): "*An individual has no need to construct his own justifications of inequity or injustice, so long as acts which are oppressive, exploiting, cruel, unjust or generally 'inhuman' are committed against certain groups whose members are socially or culturally characterised as being beyond the range within which apply certain principles (whatever they may be) of interpersonal conduct.*" The concept of the scope of justice (Opotow, 1990; Staub, 1990) is particularly important in this context. This concept refers to the existence (in people's minds) of a frontier for the application of justice principles. In other words, not all human beings are perceived to be part of our moral community. Out-groups can be included in the scope of justice if they are recategorized as in-group members, a process that can follow one of the strategies described in the previous section, that is, the development of a dual identity (Gaertner and Dovidio, 2000), a strategy that could be successful in improving intergroup relations in diverse societies.

Implicit Theories about the Nature of Human Beings and Intergroup Relations

In everyday social interactions, people create and learn collective beliefs or implicit theories or social representations (Dweck, 1999; Moscovici, 1984) that concern not only the social objects that are important for the survival of individuals and their groups but also the nature of what is typically human (Leyens et al., 2000) and the central and most useful attributes in perceiving individuals and groups (Fiske et al., 2002). These implicit theories about human nature have important consequences for intergroup relations.

Infra-Humanization Theory

While several theories have addressed the process by which out-group members are dehumanized in extreme cases of social or interpersonal conflicts (e.g., Bandura, 1999; Staub, 1990), the infra-humanization theory (Leyens et al., 2001) addressed one of the most common and pervasive forms of denial of full humanity to out-group members. This process, which has deep implications for intergroup relations, could be called "banal infra-humanization." Leyens and colleagues found that people implicitly distinguish between primary emotions (e.g., anger, joy, and fear) and secondary emotions (e.g., hope, regret, and enthusiasm) and that the latter are perceived as being learned later in life and are commonly understood to constitute an essential aspect of what makes a human being. Accordingly, Leyens and colleagues (see Vaes et al., 2012; for a review) also verified that, first, individuals are more likely to describe in-groups than out-groups in terms of secondary emotions; secondly, that in-groups are considered more able to express secondary emotions than out-group members; and thirdly, that secondary emotions but not primary emotions are more readily associated with the in-group than with out-groups. Moreover, in-group members who express a secondary emotion are seen to be more human whereas out-group members expressing the same emotion are not. Research in this domain has identified several moderators of out-group infra-humanization that largely cover the basic processes related to categorization, patterns of intergroup relations, and ideologies endorsed by group members. Specifically, it has been demonstrated that the more people perceive the in-group and the out-group as sharing a common supraordinate category (Gaertner and Dovidio, 2000), the more they attribute secondary emotions to out-groups (Gaunt, 2009). Moreover, the perception that the out-group is a threat to the in-group increases infra-humanization and the less human that the out-group is seen to be, the greater the symbolic threat that it poses to the in-group. This perception is then used to justify out-group discrimination (Pereira et al., 2009). Moreover, endorsement of SDO is associated with out-group infra-humanization (Esses et al., 2005) while other studies have shown that nationalism (but not patriotism) is linked to out-group infra-humanization.

Stereotype Content Model

This model, which was developed by Fiske et al. (2002), accentuates the importance of the content of stereotypes in intergroup relations and consistently links the basic or fundamental content dimensions according to which social judgments or impressions of social groups are formed to group status, patterns of intergroup relations, and emotions. Following the insights of Asch and Kelly, the theory assumes that categorical impression formation is based on two fundamental dimensions: warmth (i.e., honest, friendly, warm, and trustworthy) and competence (i.e., competent, capable, and skilled). Indeed, these two dimensions account for 80% of the variance in individual impression formation (Wojciszke, 2005). The model hypothesizes that these two dimensions can differentiate social groups into four meaningful quadrants. The high-warmth/high-competence quadrant typically describes in-groups while the remaining quadrants describe out-groups. Moreover, several studies have shown that perceived competition between in-groups and a given out-group lowers the perceived warmth of the out-group and that the perceived high status of an out-group increases the competence attributed to it. Regarding the consequences of placing groups into one of these clusters, research has revealed that it has an impact at both the emotional and the behavioral level. High-warmth/high-competence groups,

like in-groups, elicit pride whereas low-warmth/low-competence groups produce disgust. Ambivalent groups (high-warmth/low-competence or low-warmth/high-competence) induce mixed emotions, respectively, pity and envy. At the behavioral level, in-groups and pitied groups facilitate helping behavior but low-warmth groups elicit antagonistic behavior. Significantly, Harris and Fiske (2009) used fMRI procedures to compare activity in the mPFC (the region of the brain usually involved in the perception of individuals) in a group judgment task and verified, as predicted, that this region of the brain is activated for all groups except for low-warmth/low-competence groups.

Conclusions

The social psychology literature on intergroup relations is extensive, diversified and the result of over five decades of research. This article focused on two approaches that we consider to be prominent in the analysis of intergroup relations: on the one hand, the approach of social categorization and its connection with stereotypes, prejudice, and the relational dynamics deriving from its different configurations (e.g., recategorization, decategorization, and dual identity). Next, we examined the path from the salience of the social categorization process to the emerging salience attributed to the role of ideologies and collective beliefs on intergroup attitudes and discrimination. In this path, we showed how a full understanding of intergroup relations cannot be solely based on cognitive processes, and must attend also to motivational and emotional processes. SIT continues to represent a good example of articulation of these aspects. In the second section of this article, we demonstrated how ideologies and social norms constitute fundamental triggers of intergroup relations. Indeed, ideologies and social norms lie at the root of both harmonious and conflictual intergroup relations. Until now, most literature has considered the influence of such factors as moderators of the cognitive processes. However, the analysis of the research produced in the last years in social psychology shows how the cognitive and the ideological and normative aspects have equal explanatory power over the dynamics of intergroup relations.

Abstract

This article's focus is on interhemispheric interaction in relation to cognitive processes. Commissural fibers facilitate interhemispheric transfer, which in turn supports several cognitive functions, such as attention, memory, and language. Two major theories have been proposed to explain the specific mechanisms of interhemispheric communication, lateralization, and hemispheric specialization: the excitatory model and the inhibitory model. Neuropsychological and neuropsychiatric manifestations of callosal syndromes are also discussed.

Introduction

In the middle of the eighteenth century, scholars working in the field of acquired language impairment provided rich evidence for cerebral lateralization, a notion that contradicted the status quo ante, i.e., the belief established by Franz-Joseph Gall, that higher cognitive functions were facilitated equally by two identical hemispheres (Tesak and Code, 2008). A 100 years later, Geschwind (1965a,b) reintroduced the idea of disconnection syndromes, according to which, several neurological disorders can be attributed to interruption of white matter tracts allowing cortico-cortical communication within a neural network supporting cognitive functions, such as language and visuospatial processing (see also Catani and ffytche, 2005). This interhemispheric interaction is possible due to the commissural fibers, the greatest of all being the corpus callosum. Studies of comparative anatomy provide useful clues regarding the phylogenetic origins of the corpus callosum and hemispheric specialization (Aboitiz and Montiel, 2003; Hopkins and Cantalupo, 2008). From an evolutionary perspective, the emergence of the corpus callosum could have played an integral role in the development of cognitive functions and hemispheric lateralization (Doron and Gazzaniga, 2008; Gazzaniga, 2000). In the present article, we will discuss issues with regard to interhemispheric communication via the commissural fibers, focusing on cognitive processes and more particularly language.

Anatomy of the Commissural Fibers

The commissural fibers are white matter tracts that interconnect the two cerebral hemispheres. The majority of these bundles interconnect homologous cortical areas, but there are also fibers participating in heterotopic connections. Homotopic commissural connections interconnect corresponding cortical areas in both hemispheres, whereas heterotopic fibers connect a cortical area of one hemisphere with nonhomologous areas in the contralateral hemisphere (Knyazeva, 2013; Nieuwenhuys et al., 2008; Zarei et al., 2006). The largest commissural fiber system is the *corpus callosum*, which forms the floor of the longitudinal fissure and the roof of the lateral ventricles. It contains more than 300 million axons and interconnects the neocortical portions of the two hemispheres. These fibers are of two different types: large-diameter fibers that mediate sensory–motor coordination and small-diameter fibers that interconnect association areas (Yazgan et al., 1995). The corpus callosum is divided into a bloated posterior part, the *splenium*; a large middle part, the *body* (or *truncus*); an anterior arched part, the *genu*; and a final tapered part, the *rostrum*, which connects the genu with the lamina terminalis. There is also an intermediate, thinned part between the truncus and the splenium, the isthmus. The axons of the corpus callosum expand into the white matter of both hemispheres, thus forming the *radiation of the corpus callosum* (Nieuwenhuys et al., 2008). The rostrum connects fronto-basal cortical regions of the two hemispheres. The genu interconnects prefrontal areas and the anterior cingulated cortex. The truncus connects motor and somatosensory regions, such as the precentral cortex, the adjacent portion of the insula, and the overlying cingulated gyrus. The caudal part of the truncus along with a portion of the splenium connects cortices from the temporal–parietal–occipital junction. The isthmus connects pre- and postcentral gyri, and the primary auditory cortex. The splenium connects posterior parietal and occipital regions, as well as medial–temporal cortices (Banich, 1995; Hellige, 1993; Raybaud, 2010). Even though callosal fibers typically project to homologous hemispheric regions (Hellige, 1993; McCulloch and Garol, 1941; Putnam et al., 2008), a small proportion projects to heterotopic regions (Clarke and Zaidel, 1994; Cook, 1984; Rakic and Yakovlev, 1968). Another commissural fiber system is the *anterior commissure*. This is a transversely oriented axon bundle and consists of two parts: a small anterior limb which interconnects olfactory cortices and a larger posterior limb which interconnects anterior areas of the middle and inferior temporal gyri. The third commissural fiber system interconnecting the two cerebral hemispheres is the *hippocampal commissure*, a part of the fornix located below the splenium that connects the two hippocampi (Nieuwenhuys et al., 2008).

Excitation versus Inhibition

Researchers have yet to establish a clear-cut pattern with regard to regulation of interhemispheric communication via the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54039-2

commissural fibers (Liederman, 1998). In terms of neurochemistry, the largest commissural fiber system, the corpus callosum can be characterized as a bundle of excitatory fibers, since the most common neurotransmitter of the callosal axons is glutamate (Conti and Manzoni, 1994). However, callosal signals can be inhibitory, due to the presence of inhibitory interneurons (Kawaguchi, 1992). Overall, the final functional effect of callosal connections can be either excitatory or inhibitory, depending on a variety of factors, including neurotransmitters, receptors, and interneurons. Due to lack of concluding evidence, the debate on a hypothesized excitatory versus inhibitory callosal function remains unresolved, focusing on two opposing models (van der Knaap and van der Ham, 2011; Bloom and Hynd, 2005).

The first model comprises theories of inhibition. According to it, the size of the corpus callosum is analogous to the degree of interhemispheric connectivity (Aboitiz et al., 1992a,b), which in turn is positively correlated with lateralization emerging due to interhemispheric inhibition (van der Knaap and van der Ham, 2011). The inhibitory model presumes that, during development, one hemisphere can inhibit the other via the corpus callosum, thus becoming dominant for a particular function (Hellige, 1993). There is reported evidence suggesting an essential role of inhibitory callosal action during ontogeny (Dennis, 1976). This phenomenon – called *metacontrol* – allows intrahemispheric processing and aids hemispheric asymmetry. It is based on the idea that transferring information between hemispheres and interhemispheric integration is energy- and time-consuming; therefore intrahemispheric processing could be more efficient with regard to simple tasks (Urgesi et al., 2005; Welcome and Chiarello, 2008). During the last four decades, many scholars have postulated several theories of inhibition. For example, Kinsbourne (1975) claimed that activation in the two hemispheres is mediated by the corpus callosum to be inversely proportional, in the context of a continuous inhibitory interaction of cortical areas connected by callosal fibers. On the other hand, Cook (1984) proposed the homotopic inhibition theory, according to which, the corpus callosum interconnects homologous areas of the two hemispheres in an inhibitory mode, and these areas also connect to adjacent cortical regions in a reciprocally inhibitory fashion. Although many variations of the inhibitory model have been proposed, all theories of inhibition state that hemispheric asymmetry is accomplished – at least in part – via callosal inhibitory mediation, which ultimately leads to hemispheric dominance for a given function, and that the degree of lateralization is proportional to the size of the corpus callosum (Hellige, 1993; Bloom and Hynd, 2005).

There are a few studies supporting the inhibitory model, by demonstrating independent intrahemispheric processing when verbal stimuli are presented to either of the two hemispheres (Hellige, 1993) or bilateral parallel processing for complex tasks (Banich and Belger, 1990). Further support is provided by dichotic listening studies, where different stimuli are presented simultaneously in each ear. According to Clarke et al. (1993), corpus callosum size is not related to laterality, but it is negatively correlated with superior ear accuracy, therefore possibly associated with the degree of functional interhemispheric inhibition. Research on the aging of the corpus callosum can also offer evidence in favor of the inhibitory view. A recent study on the possible relation between age-related degeneration of the corpus callosum and interhemispheric inhibition showed that reduced resting interhemispheric connectivity in older adults was associated with increased ipsilateral motor cortex recruitment during a simple motor task (Langan et al., 2010). The authors suggest that age-related reduced callosal connectivity reflects a deficient inhibition of the nondominant hemisphere during a simple motor task, a phenomenon resulting in greater reaction times, thus impaired performance. Putnam et al. (2008) combined functional magnetic resonance imaging and diffusion tensor imaging to investigate the relationship between callosal structure and bilateral cortical activity in healthy young adults during a verbal encoding task involving semantic judgment. While task performance was associated with increased activity in the left inferior prefrontal cortex as expected, they found that participants with low anterior callosal fractional anisotropy values demonstrated significantly greater activity in the right homologous region, compared to participants with high anterior callosal fractional anisotropy values. These results are consistent with the inhibitory model in the sense that a thinner corpus callosum would result in decreased interhemispheric inhibition indicated by increased activation of the homologous contralateral cortical area. Finally, research on developmental dyslexia suggests that the size of the corpus callosum is smaller in dyslexic children, and that splenium and genu sizes are associated with reading achievement (Hynd et al., 1995). Overall, reported data supporting the inhibitory model are scarce. It should be also noted that a study specifically designed to test Cook's homotopic inhibition theory failed to find any supporting evidence for interhemispheric inhibition mediated by the corpus callosum (Chiarello et al., 1995).

The second model is based on theories of excitation. It postulates that integration of information is enforced by interhemispheric excitation via the commissural fibers, and that the size of corpus callosum decreases as hemisphere laterality increases (Bloom and Hynd, 2005). The first evidence in favor of this view comes from early callosotomy studies (Gazzaniga and Sperry, 1967; Gazzaniga et al., 1963) showing that these patients demonstrated difficulties in integrating information received exclusively by the right or the left hemisphere. Subsequent studies confirmed that even if split-brain patients recover well a few years post surgery, being able to function successfully in everyday living activities (Sergent, 1983), they show a variety of deficits in the context of a disconnection syndrome (Banich, 1995; Crandall, 1985; Gazzaniga, 1970; Gazzaniga and Sperry, 1967; Lassonde, 1986). In sum, split-brain studies support the core idea of the excitatory model, by presenting evidence that the corpus callosum is essential for cognitive functions, through facilitating interhemispheric transfer and integration of sensory information.

One of the fundamental predictions of this model is that hemispheric asymmetry and size of the corpus callosum are inversely proportional. Studies in this direction have confirmed this hypothesis. Anatomical postmortem (Aboitiz et al., 1992a,b; Aboitiz et al., 1992) and *in vivo* (Dorion et al., 2000) studies have demonstrated an inverse association

between the size of the corpus callosum and asymmetry of homologous cortical areas. Research utilizing specialized neuropsychological tests and structural MRI has shown that performance on behavioral laterality measures is significantly negatively correlated with corpus callosum size (Clarke and Zaidel, 1994; Yazgan et al., 1995). Galaburda (1984) suggested that stronger interhemispheric connectivity leads to greater symmetry, thus indicating that emerging asymmetry during development is due to lack of interhemispheric excitatory connections. The logical consequence of this assumption is that a smaller corpus callosum would be associated with increased functional laterality, which is essential for cognitive functions, especially language – a rather lateralized function. Geschwind and Galaburda (1985) have provided anatomical evidence that the degree of hemispheric asymmetry (focusing on left language areas and their homologous areas in the right hemisphere) differs between individuals with dyslexia and normal readers. Galaburda (1995) suggests that developmental dyslexia is related to a larger right planum temporale, which interferes with the homologous dominant left area during language processing. He attributes this unexpected asymmetry to insufficient pruning. The aforementioned interference of the nondominant right planum temporale is supposed to manifest itself via the corpus callosum. This phenomenon would be aided by increased callosal connections, which could be also due to inadequate pruning during development (Galaburda et al., 1990). It should be although noted that while most researchers find abnormalities with regard to the size (Duara et al., 1991; Hynd et al., 1995; Larsen et al., 1990; von Plessen et al., 2002) and shape (Robichon et al., 2000; von Plessen et al., 2002) of the corpus callosum of individuals with developmental dyslexia, the reported data are contradicting. Some studies have found a larger corpus callosum in dyslexic readers (Duara et al., 1991; Larsen et al., 1990), others have failed to find any difference in the size of the corpus callosum between healthy controls and persons with developmental reading or language disability (Preis et al., 2000), and there are also studies providing evidence in favor of the inhibitory model (reporting smaller corpus callosum areas in dyslexics compared to normal readers) (Hynd et al., 1995; von Plessen et al., 2002). In view of such conflicting evidence, Bloom and Hynd (2005) stress the idea that the corpus callosum's size and shape may not be related to developmental dyslexia and, consequently, to reading ability.

Evidence for an excitatory role of the corpus callosum also comes from studies including patients with acquired or developmental callosal lesions. Callosotomies have been performed for many decades on epileptic patients, in order to constrain seizures. The idea behind these surgeries is that seizures from one hemisphere propagate to the other via the corpus callosum. Therefore, the effectiveness of callosotomy in preventing interhemispheric spreading of the epileptic seizures provides evidence supporting the excitatory function of the callosal fibers (but see also Roberts (1999) for a proposed inhibitory callosal function in such patients). Individuals with congenital agenesis of the corpus callosum typically demonstrate subtle linguistic and visuospatial deficits (Chiarello, 1995), similar to split-brain patients (Gazzaniga et al., 1963). Moreover, research on callosal agenesis contradicts the inhibitory view, since hemispheric lateralization develops normally and typically lateralized functions are not represented bilaterally in such patients (Lassonde, 1986). Finally, comparative anatomy research from the field of evolutionary biology provides further support to the excitatory view, by demonstrating that as laterality increases, corpus callosum size decreases across primates (Hopkins and Rilling, 2000). These data offer insight into emerging hemispheric lateralization in terms of phylogeny, and indicate that brain asymmetry evolved in Hominidae due to reduced interhemispheric connectivity.

Overall, one can find evidence for both theories in the relevant literature. However, reality with regard to interhemispheric interactions may not correspond exclusively to an inhibitory or an excitatory model. On the contrary, there may be several ways of such interactions, depending on the processing demands of a given task. Thus, these two main types of interaction are not mutually exclusive, and commissural fibers such as the corpus callosum may be inhibitory or excitatory, on the basis of specific needs for a particular cognitive function (type of stimuli, processing demands, hemispheric specialization, etc.). This proposed flexibility of the corpus callosum is suggested to increase processing efficiency in terms of time and overall performance. In some instances, when one hemisphere is superior to the other for a given task (e.g., the left hemisphere for processing linguistic information), independent operation of the hemispheres and intrahemispheric processing might be more advantageous, and therefore callosal isolation would be beneficial. On the other hand, when a particular type of stimulus can be equally processed by both hemispheres, sharing of hemispheric resources and interhemispheric cooperation might be more advantageous, and therefore callosal excitation would increase processing efficiency and performance (Bloom and Hynd, 2005; Schulte and Müller-Oehring, 2010). From a phylogenetic perspective, the emergence of anatomical and functional lateralization per se can be explained by either of the two theories. On the basis of the inhibitory claim, there could be an isolation of the contralateral hemisphere via the corpus callosum, thus leading to asymmetrical hemispheric development. In contrast, an excitatory function of the corpus callosum could have allowed unilateral mutations during interhemispheric integration. These mutations could provide a substrate for the evolutionary origins of lateralization (van der Knaap and van der Ham, 2011).

Commissural Fibers and Cognitive Functions: Interhemispheric Cooperation, Information Transfer, and Integration

There are two types of callosal fibers in terms of size and myelination. Thick, heavily myelinated fibers with a large diameter can save time by fast transmission of sensory and motor information, while thinner, less myelinated fibers with a smaller diameter demonstrate slower transmission rates between association cortical areas (Aboitiz, 1992; Aboitiz and Montiel, 2003; Bloom and Hynd, 2005; Knyazeva, 2013; Ringo et al., 1994). In any case, interhemispheric transfer and integration is a time- and energy-consuming process and

it is thus not always beneficial. However, transferring information between hemispheres can be proved to be advantageous when the cognitive load is increased. Simple tasks can be processed intrahemispherically, while highly demanding complex tasks may require bilateral activation and interhemispheric cooperation (Banich, 1998; Banich and Belger, 1990; Braver et al., 1997; Smith et al., 1996; Welcome and Chiarello, 2008). Therefore bilateral processing is preferred over processing within a single hemisphere when load-dependent benefits outweigh time and energy costs. Hemispheric lateralization for higher cognitive functions, such as the left-hemisphere dominance for language and specialization of the right hemisphere for visuospatial attention, has been argued to be a consequence of interhemispheric connectivity. It has been suggested that, in the course of the primates' evolution, intrahemispheric processing, and consequently hemispheric specialization, was induced by increased time constraints of callosal conduction delay (Hopkins and Rilling, 2000).

Callosal connections are traditionally associated with transfer and integration of sensorimotor information (Banich, 1998; Fling et al., 2011; Franz et al., 2000; Gerloff and Andres, 2002; Johansen-Berg et al., 2007; Wahl et al., 2007). However, contemporary research indicates the involvement of the corpus callosum in higher cognitive functions, and the relationship between the integrity of white matter microstructure in this commissural fiber system and performance on a variety of cognitive tasks (Roberts et al., 2013). Several studies point out that bihemispheric interaction is essential for visuospatial attention, object recognition, and processing of complex visual stimuli (Baird et al., 2005; Banich, 1998; Banich et al., 2000; Corbetta et al., 2005; Kinsbourne, 1977; Kinsbourne and Bruce, 1987; Reuter-Lorenz et al., 1990; Schulte et al., 2001; Skiba et al., 2000). Clinical research has shown that the integrity of the corpus callosum is essential for selective attention and conflict processing, in the context of interhemispheric transferring of information within a fronto-parietal attention neural network (Schulte et al., 2006). Studies on visual perception, including patients with callosal abnormalities due to normal aging (Müller-Oehring et al., 2007), commissurotomy (Robertson et al., 1993), HIV infection (Müller-Oehring et al., 2010), and alcoholism (Müller-Oehring et al., 2009), showed that compromised integrity of the corpus callosum is related to impaired local–global processing of visual stimuli. (The process of decomposing the visual world into distinct component features and the re-integrating the latter into a complex visual stimulus). Schulte and Müller-Oehring (2010) suggest that such findings indicate that lateralized whole-part perceptual integration is mediated by the corpus callosum and more specifically, "anterior callosal integrity appears to mediate local-global interference (callosal inhibition), whereas posterior callosal integrity seems to mediate local-global facilitation (callosal cooperation)" (p. 183).

Even though the corpus callosum is the greater commissural fiber system, therefore the main white matter pathway supporting interhemispheric connectivity, there are also two additional subcortical commissures, as mentioned earlier: the anterior commissure, which connects the two cerebral hemispheres at the lateral striatal ridge, and the hippocampal commissure, which connects two hippocampi. In terms of ontogeny, both of these structures develop earlier in gestation compared to the corpus callosum (Bloom and Hynd, 2005). Studies involving 'split-brain' patients (i.e., patients who have undergone callosotomy) have shown that such individuals appear to be unaffected with regard to general cognitive capacity, sense of self, and affect, and retain certain cognitive abilities, such as integrating some aspects of spatial attention and emotional information, despite the absence of callosal interhemispheric connections (Sperry et al., 1979; Gazzaniga, 1970). (It should be however noted that cognition does not remain entirely unaffected. Even though several cognitive functions, such as verbal intelligence and problem-solving capacity remain intact, specific deficits, such as in coordination, stereognosis, free recall, and short-term memory have been reported (Gazzaniga, 2000; Josheph and Bannister, 2001; Phelps, Hirst, and Gazzaniga, 1991; Zaidel and Sperry, 1974).) Moreover, acallosal patients (individuals with congenital agenesis of the corpus callosum), often show only mild cognitive deficits (Josheph and Bannister, 2001). Their difficulties remain usually undetected (in some cases callosal agenesis is revealed postmortem, after autopsy) throughout their lifespan. Normally these patients are identified only when a comorbid condition requires structural imaging (Darby and Walsh, 2005; Harris, 1995; Kasselimis and Potagas, unpublished data; Zaidel et al., 2003). Taken together, clinical data from split-brain and acallosal patients suggest that at least for some cognitive functions an intact corpus callosum does not seem to be a prerequisite, and interhemispheric transfer and integration of information may be supported by the anterior and the hippocampal commissure (but see also Gazzaniga, 2000).

Interhemispheric Interaction and Language

Since the paradigm-shifting case studies of Pierre Paul Broca (1861a,b,c, 1863), it is widely accepted that language is mainly facilitated by the left hemisphere. This specialization is also designated by functional and structural hemispheric asymmetries (Steinmann and Mulert, 2012). Rich research evidence derived from split-brain patients reveals that phonology, lexicon, and syntax are supported mainly by left-hemisphere cortices, while the opposite hemisphere appears to be rather limited regarding language and it can process only lower-level linguistic material (Baynes, 1990; Baynes and Eliassen, 1998; Baynes and Gazzaniga, 1988; Baynes et al., 1997, 1995, 1970, 1983, 2000; Gazzaniga and Miller, 1989; Gazzaniga et al., 1984, 1979; Gazzaniga and Sperry, 1967; Reuter-Lorenz and Baynes, 1992; Sidtis et al., 1981; Zaidel, 1991; Zaidel and Peters, 1981; Zeidel and Seibert, 1997).

Even though it is the left hemisphere that mainly supports language, interhemispheric cooperation has been shown to be involved in linguistic functions. Gazzaniga (2000) argues that specific callosal fibers transfer semantic representations and word information, essential for processing verbal stimuli. In terms of anatomy, there are several language-related cortical regions of the left hemisphere interconnected with their right homologues via the corpus callosum. It has been further claimed that the structural characteristics of such

connections relate to performance on speech perception tasks (for a review, see Steinmann and Mulert, 2012). Some studies argue in favor of a topographically specific functional role of the corpus callosum. For example, the posterior portion of the greater commissural fiber bundle, including the splenium and the perisplenial white matter, is shown to be crucial for phonological awareness (Dougherty et al., 2007) and the interhemispheric interplay between prosodic and syntactic information (Friederici et al., 2007). While syntax is facilitated mainly by the left hemisphere and prosodic features of speech are processed by right hemisphere cortices, the interaction of these functions relies on interhemispheric communication via the posterior corpus callosum (Friederici et al., 2007). Taking into account the accumulating data on the role of commissural fibers in language processing, Friederici (2011) corroborates the idea that the corpus callosum "builds the brain basis for the integration of local syntactic and prosodic features during auditory speech comprehension, as it connects the brain regions in which syntax and prosody are computed" (p. 1384). Finally, it has been argued that interhemispheric connections also subserve language comprehension in the context of processing semantic features of verbal information. In his recent review, Jung-Beeman (2005) suggests that current neuroimaging data support a framework for verbal semantic processing, which consists of three components: bilateral activation, integration, and selection. These components are localized bihemispherically and comprise a bilateral interactive semantic network.

Callosal Syndromes: Neuropsychological and Neuropsychiatric

Compromised integrity of commissural fibers has been related to many clinical conditions, such as perceptual deficits (Zaidel et al., 2003); dyslexia (Klingberg et al., 2000; Zaidel et al., 1998); stuttering (Chang et al., 2008; Sommer et al., 2002); neuropsychiatric features of alcoholism (Harper and Kril, 1988, 1990; Harper and Matsumoto, 2005; Pfefferbaum and Sullivan, 2002, 2005; Pfefferbaum et al., 2006; Tarnowska-Dziduszko et al., 1995); bipolar disorder (van der Knaap and van der Ham, 2011); neurodegenerative diseases, such as Alzheimer's disease, frontotemporal dementia, and amyotrophic lateral sclerosis (Murray et al., 2006); cognitive impairment and fatigue in multiple sclerosis (Yaldizli et al., 2013; van der Knaap and van der Ham, 2011); dysgraphia (Buklina, 2005); and attention-deficit hyperactivity disorder (McNally et al., 2010; Schnoebelen et al., 2010; van der Knaap and van der Ham, 2011). The detailed description of all possible impairments due to commissural fibers' abnormalities is beyond the scope of this article; therefore we will briefly discuss some of the main neuropsychological and neuropsychiatric callosal syndromes.

Pure alexia (or alexia without agraphia) is among of the renowned disconnection syndromes. It was originally described by Déjérine (1892), who reported the case of a stroke patient who had no difficulties in speech, auditory comprehension, or writing, nevertheless was unable to read. The patient's lesion was located in the left occipital lobe and included portion of the splenium. Dejerine suggested that the syndrome was due to the fact that visual information could not reach the language region in the left hemisphere. Several cases of alexia with various underlying neurological etiologies have been reported since then, the majority of which is attributed to some kind of interhemispheric disconnection. Pure alexia is usually suggested to be the result of a lesion interrupting communication between visual areas of both occipital lobes with language perisylvian areas of the left hemisphere (Coslett, 2003).

Among the psychiatric disorders that researchers have attempted to interpret under a broad theory of disconnectionism, schizophrenia has surely the first place. Wernicke was the first to propose a functional disconnection in the brain in schizophrenia (Wernicke, 1906), and this notion came to light again during the 1990s (Friston and Frith, 1995). A disconnection hypothesis of schizophrenia holds that failure in cognition arises from pathophysiology, i.e., impairment in functional integration within the brain. Friston argues that the pathophysiology in schizophrenia is due to abnormal connections within a brain with abnormal plasticity. An anomaly in connectivity is a matter of discontinuation in the synaptic flux (Friston, 1998). Schizophrenic symptoms in adults could be then evolved from dysplastic fatal brain development (Bullmore et al., 1997). The classic disconnection hypothesis though, may not account for possible changes within or between the hemispheres. Advances in imaging studies and neurostatistical techniques during the last decade offered us adequate evidence both for structural and functional connectivity for widespread disconnection in resting-state brain networks, especially in the default network (Guo et al., 2013). An investigation of abnormal interhemispheric connectivity in schizophrenia emphasizes the role of the anterior part of the corpus callosum (Crow, 1998). Also, the size of the anterior commissure as measured with diffusion tensor imaging has also been found to play a role in schizophrenia (Choi et al., 2011). Guo et al. (2014) have suggested a weakening of functional connectivity between the two brain hemispheres involving a number of cortical and limbic regions.

Autistic spectrum conditions form a diagnostic umbrella of a wide range of pervasive neurodevelopmental disorders with an onset in early childhood and a life-long symptomatology. Deficits in cognition, emotional processing, and social functionality are being studied thoroughly at the neurological level for the past decade, in many prior imaging studies (Castelli et al., 2002; Just et al., 2004; Koshino et al., 2005, 2008). Abnormal long-range functional connectivity has been studied in recent explanatory models of autism. The matter of decreased hemispheric connectivity seems a quite plausible explanation for the defective neuronal activity in autism, and is one that needs further empirical clarification. Two main models have tried to account for a decreased neuronal connectivity, especially in the frontal regions (Catarino et al., 2013): the weak central coherence model and the executive dysfunction model. As regards cognitive deficits in autism, paradigms involving task-related regions of interest have pointed out working memory, executive function, face processing, motor function, and language. Also, along with analyses from resting-state

paradigms, researchers have identified a pattern of local overconnectivity but long-distance underconnectivity in autism (Anderson et al., 2010). In imaging studies, long-range white matter pathology in autism is now evident, with the corpus callosum's volume being one of the most reliable measures: decreased callosal size is one systematically shown structural finding in autism. Another reliable measure in searching for structural abnormalities in autistic disorders is the size of the genu (Mason et al., 2008).

Clinical features of the alien hand syndrome are abundantly described in the neuropsychological literature, mainly because of its dramatic appearance. Alien hand syndrome, often paraphrased as 'the anarchic hand,' is a neurological condition in which lesions in the anterior part of the corpus callosum produce involuntary movement, while the patient fails to distinguish the affected hand from the physician's hand when these are placed in the patient's unaffected hand (Bundick and Spinella, 2000). Long before Dr Strangelove and his cinematic intermanual conflict, Dr Kurt Goldstein described the first known alien hand case, where a right-handed woman complained of her left hand being estranged and belonging to another person, while it acted on its own (Goldstein, 1908). Later in the 1960s, Norman Geschwind was the first to applaud Goldstein's efforts in stressing "the non-unity of the personality in patients with callosal section and its possible psychiatric effects," in his classic *Brain* paper (Geschwind, 1965b, p. 638). Today, a widely accepted definition for the alien hand syndrome in current neurology requires "a feeling that one limb is foreign or 'has a will of its own,' *together with* observable involuntary motor activity" (Doody and Jankovic, 1992, p. 807). Three different varieties of the alien hand syndrome have been described, with the first two sharing a frontal variant and being easily dissociable – at least theoretically (Bundick and Spinella, 2000). The first one affects the dominant hand and is found in lesions of the language medial frontal cortex and the anterior corpus callosum, while the second affects the nondominant hand and is found after lesions of the corpus callosum alone (Feinberg et al., 1992; Goldberg and Bloom, 1990). A third variety, far less common than the previous two, is reported after posterior lesions, either in corticobasal degeneration or in cerebrovascular accidents, where the protagonist is usually the nondominant hand (Gibb et al., 1989; Ventura et al., 1995).

Abstract

Self-concept is an important outcome variable that facilitates attainment of other desirable outcomes. Self-concept formation is based in part on the frames of reference or standards of comparison used to evaluate one's accomplishments. The internal/external frame of reference model posits dimensional comparisons such that accomplishments in one domain are used as a basis of comparison for evaluating accomplishments in other domains, along with the accomplishments of other individuals (social comparison). Based on extensive support in educational settings that generalizes across gender, age, and nationality, it explains why high achievement in one domain (e.g., mathematics) can have negative effects on self-concepts in another domain (verbal).

A critical advance in psychology has been the growing emphasis on a positive psychology that focuses on how healthy, normal, and exceptional individuals can get the most from life (e.g., Marsh, 2007; Marsh and Craven, 2006; Seligman and Csikszentmihalyi, 2000). Consistent with this emphasis, positive self-concept and its enhancement have been the focus of research and interventions in many disciplines of psychology and the social science more generally. Self-concept is also an important mediating factor that facilitates the attainment of other desirable outcomes, such as choice behavior, planning, persistence, and subsequent accomplishments. Individuals are likely to accomplish more and perform better if they feel competent in what they do, are confident, and feel positively about themselves. However, relations between self-concept and desirable outcomes are often reciprocal, each being both a cause and an effect of the other. Programs and institutions that undermine self-concept are also likely to have negative effects on accomplishments.

There has been substantial improvement in the quality of self-concept research because of a synergy between better measurement instruments, theoretical models, quantitative methodologies, and research designs. The cornerstone of this resurgence was the classic review article by Shavelson et al. (1976). They posited self-concept as a multidimensional hierarchical construct and their structural model became the blueprint for the development of future self-concept instruments (Marsh, 2007). Shavelson et al. posited different facets of academic self-concept (ASC) to be substantially correlated and to form a single higher-order ASC factor, consistent with relations between achievements in different school subjects. However, subsequent research revealed that math self-concept (MSC) and verbal self-concept (VSC) in particular were nearly uncorrelated, leading to the Marsh/Shavelson revision (Marsh and Shavelson, 1985) that posited two higher-order ASC factors (math/academic and verbal/academic). In this model, it was proposed that underlying the verbal–math ASC factors was a continuum of ASC factors ranging from VSC at one end to MSC at the other, with an ordering of academic self-concepts in other domains along this continuum (see **Figure 1**).

The Internal/External Frame of Reference Model: Theoretical Basis

Self-concept theory emphasizes that perceptions of the self cannot be adequately understood if the role of frames of reference is ignored (Marsh, 2007). The same objective characteristics and accomplishments can lead to disparate self-concepts, depending on the frames of reference or standards of comparison that individuals use to evaluate themselves, and these self-beliefs have important implications for future choices, performance, and behaviors. The two most frequently posited frames of reference are based on social and temporal comparisons (Möller, 2005; Möller et al., 2009, 2011); self-perceptions are based in part on how current accomplishments compare with our past performances (temporal comparisons) and how our accomplishments compare with those of others within our current context (social comparisons; e.g., classmates in our school or class). Particularly in educational settings, a growing body of research based on the internal/external frame of reference (I/E) model (Marsh, 1986) demonstrates that self-perceptions may also be the result of internal comparisons, in which accomplishments in one school subject can serve as a frame of reference for another school subject – hereafter referred to as 'dimensional' comparisons (e.g., Möller and Köller, 2001a; Möller and Marsh, 2013; Möller et al., 2009; see also Möller et al., in this volume).

Dimensional comparison research has largely revolved around the I/E model, which initially was developed to explain why MSC and VSC are almost uncorrelated, even though corresponding areas of academic achievement are substantially correlated (typically 0.5–0.8, depending on how achievement

Figure 1 The Marsh/Shavelson revised academic self-concept model, which includes a wider variety of specific academic facets. Adapted with permission from Marsh, H.W., 2007. Self-concept Theory, Measurement and Research into Practice: The Role of self-concept in Educational Psychology. British Psychological Society, Leicester, UK.

is measured; for further discussion, see Marsh, 2007). People think of themselves as mostly math or mostly verbal persons, even though individuals who are good at one also tend to be good at the other (see Marsh, 1986). Why is there this stark contrast between academic self-perceptions and corresponding objective accomplishments? According to the I/E model, self-concept in a particular school subject is formed in relation to an external (social comparison) reference in which students compare their self-perceived performances in a particular school subject with the perceived performances of other students in the same school subject, and an internal (dimensional, ipsative comparison) reference in which students compare their own performances in the particular school subject with their own performances in other school subjects. Hence, students may have a favorable MSC if math is their best subject, even if they are not particularly good at math relative to other students. The joint operation of these processes, depending on the relative weight given to each, is consistent with the near-zero correlation between MSC and VSC that led to the revision of the Shavelson model (Marsh, 2007).

Tests of the I/E model typically are conducted when math and verbal achievements are regressed on MSC and VSC (see Figure 2). The external comparison process predicts that good math skills lead to higher MSCs and that good verbal skills lead to higher VSCs. According to the internal dimensional comparison process, however, good math skills lead to lower VSCs once the positive effects of good verbal skills are

Figure 2 Cumulative references to the self-concept 'internal/external frame of reference' from Google Scholar. Only those publications with at least one other citation are included.

controlled for: The better I am at mathematics, the poorer I am at verbal subjects, relative to my good math skills. Similarly, better verbal skills lead to lower MSCs once the positive effects of good math skills are controlled for. In models used to test this prediction (see Figure 2), the horizontal paths leading from math achievement to MSC and from verbal achievement to VSC (the gray horizontal lines in Figure 2) are predicted to be substantially positive (indicated as ++ in Figure 2). However, the cross paths leading from math achievement to VSC and from verbal achievement to MSC (the dark lines in Figure 2) are predicted to be negative.

Empirical Support for the I/E Model

From the first publication in 1986, I/E research has developed into a mature and growing research area. Indeed, Google Scholar indicates that there have been more publications on this topic in the last 8 years than in all previous years combined, with 31% of all publications occurring in the last 5 years (see Figure 3). Marsh (1986) first proposed the I/E model and summarized the results of 13 studies of the relations between math and verbal achievements and self-concepts in the corresponding domains. Although there were consistently high correlations between math and verbal achievements (0.42–0.94), there were weak or even negative correlations between MSCs and VSCs (−0.10 to 0.19). In the I/E path diagram (Figure 2), the (horizontal) paths from math achievement to MSC and from verbal achievement to VSC were substantial and positive. However, the (cross) paths from math achievement to VSC and from verbal achievement to MSC were significant and negative. Subsequent research (see reviews by Marsh, 2007; Möller et al., 2009) provides strong support for the generalizability of these findings.

Figure 3 The 'classic' internal/external frame of reference (I/E) model relating verbal and math achievements to verbal and math self-concepts. According to predictions from the I/E model, the horizontal paths from achievement to self-concept in the matching domains (content area) are predicted to be substantial and positive (++), whereas the cross paths from achievement in one domain area to self-concept in a nonmatching domain (shaded in gray above) are predicted to be negative (−). In the present investigation, we evaluate the generalizability of these predictions to the science domain, relating science and math achievements to science and math self-concepts. Adapted with permission from Marsh, H.W., 2007. Self-concept Theory, Measurement and Research into Practice: The Role of Self-concept in Educational Psychology. British Psychological Society, Leicester, UK.

Importantly, the I/E framework has recently been extended to predict long-term educational choices. For example, Nagy et al. (2008) found that math achievement, task value, and self-concept have a positive effect on choosing math-related advanced courses but a negative effect on choosing verbal related advanced courses. Parker et al. (2012) extended this research, showing that math and verbal achievement and self-concept positively predicted final school year matriculation results and university entry. However, math achievement and self-concept positively predicted entry into university majors in math and the physical sciences but negatively predicted entry into the humanities. Such research suggests that dimensional comparison processes associated with the I/E model mean that young people use a profile of their perceived strengths and weaknesses in order to make educational decisions.

Most I/E studies (see Marsh, 2007) are based on cross-sectional or longitudinal and quasiexperimental studies. However, Möller and colleagues (e.g., Möller and Köller, 2001a; also see Möller and Marsh, 2014; Pohlmann and Möller, 2009) found support for the I/E model in true experimental studies with randomly assigned students, illustrating how experimentally manipulated feedback on achievement in one subject area had an inverse effect on self-concept in a different area. In a series of studies, Möller and Köller (2001a; Pohlmann and Möller, 2009) independently manipulated the external comparison process based on performance feedback relative to other students, and the internal comparison process based on feedback relative to performance by the same student on achievement on two subject-specific tasks. In each study, dimensional comparison information had the expected effects (e.g., positive math feedback enhanced MSC and weakened VSC). These true experimental studies provided strong support for both the dimensional and external comparison processes posited in the I/E model, and the causal interpretations of the two processes. Examining the spontaneous occurrence of dimensional comparisons with two introspective diary studies, Möller and Husemann (2006) confirmed that students spontaneously carry out dimensional comparisons in everyday life, with contrast effects from one domain to self-evaluations and emotions in the other (for more details on dimensional comparison processes, see Möller et al., this volume).

Meta-Analysis of I/E Studies

Möller et al. (2009) conducted a meta-analysis of 69 data sets ($n = 125\,308$) for studies that simultaneously evaluated the effects of math and verbal achievements on MSC and VSC. Across all studies, math and verbal achievements were highly correlated (0.67), but self-concepts were nearly uncorrelated (0.10). Path coefficients from achievement to ASC in the matching domains were positive (0.61 for math, 0.49 for verbal) but negative from math achievement to VSC (−0.21) and verbal achievement to MSC (−0.27). Support for the I/E predictions generalized across age group, gender, and country, leading the authors to conclude, "The results of our meta-analyses indicate that the relations described in the classical I/E model are not restricted to a particular

achievement or self-concept measure or to specific age groups, gender groups, or countries" (p. 1157).

A particular strength of meta-analysis is the ability to evaluate the generalizability of the results, but the strength of these tests depends upon the available data. Möller et al. found good support for the generalizability of the I/E model in relation to age, gender, and country of residence. However, there was significant study-to-study variation in the sizes of relations among I/E variables, suggesting that the results did not generalize completely. Remarkably, they found no significant differences for country of residence or age. However, most of the samples were from Western and several Asian countries (7 Asian, 12 Australian, 7 USA, and 39 European samples were included in the analysis of country as a moderator). Although the meta-analysis included responses by students from 'other nationalities,' the authors argued that the number of studies from these 'other' countries was too small to be included in analyses of country as a moderator. Similarly, it is surprising that Möller et al. found no differences as a function of age, given developmental models of how self-concept formation varies as a function of age (e.g., Marsh, 1989, 2007; Wigfield and Eccles, 2002). However, because of the paucity of available studies with young children (only 3 of 69 samples reported results for children in grade 4 or younger) the generalizability of this finding was not strong. Subsequent research focused on these apparent limitations in existing research on cross-cultural and developmental generalizability.

Cross-Cultural and Developmental Generalizability

Cross-cultural research seeks to test the cross-cultural generalizability of a theory, to establish its scope and identify cultural boundary conditions (Marsh and Hau, 2004). The I/E model has been validated in more than 35 countries including many non-English-speaking Western, Asian, and Islamic countries (Marsh et al., 2014; Marsh and Hau, 2004; Möller et al., 2009). Marsh and Hau (2004) provided persuasive support for the cross-cultural generalizability of the I/E model, based on the PISA 2000 database: nationally representative samples of 15-year-olds from 26 countries (total $N = 55\,577$). As predicted, the two horizontal paths relating math achievement to MSC (0.44) and reading achievement to VSC (0.47) were substantial and positive, whereas the two cross paths leading from verbal achievement to MSC (−0.20) and mathematics achievement to VSC (−0.26) were negative. Although the correlation between math and verbal achievement factors ($r = 0.78$) was very large, the corresponding correlation between MSC and VSC factors ($r = 0.10$) was substantially lower. In multigroup confirmatory factor analysis and structural equation modeling tests of invariance, even the highly restrictive model of total invariance (i.e., requiring every parameter to be the same in all 26 countries) provided a good fit to the data that differed only slightly from the baseline model with no invariance constraints. These results support the cross-cultural generalizability of the measures and the relations among them across these 26 countries.

As part of their meta-analysis of I/E studies, Möller et al. (2009) demonstrated that results based on the 26 PISA countries generalized well to those from the remaining samples. Noting the complementary strengths and weaknesses associated both with meta-analyses such as that of Möller et al., and with large, comprehensive primary studies, such as the Marsh and Hau (2004) study using PISA data, Möller et al. concluded "the juxtaposition of this meta-analysis with the large PISA primary study is particularly important. The similarity in the pattern of results provides important support for the I/E model" (p. 1160). Clearly, the results of this meta-analysis, in combination with previous research, provide very strong support for the I/E model. Nevertheless, because the PISA data were based on 15-year-old students from mostly Western and several Asian countries, neither the meta-analysis nor the PISA study provided strong tests of the developmental generalizability of the I/E model or even of cross-cultural generalizability beyond Western and Asian countries.

These concerns were addressed in part by the Marsh et al. (2014) study of math and science constructs, based on the Trends in International Mathematics and Science Study (TIMSS) 2007 data. This demonstrated support for the generalizability of I/E predictions in relation to math and science domains, intrinsic motivation, and self-concept. The findings, based on nationally representative matched samples of fourth and eighth grade students from 13 diverse countries, were largely generalizable over age and nationality. Averaged across all 26 (13 countries × 2 age cohorts) groups, horizontal paths from matching achievement domains were all significantly positive (.524, standard error (SE) = 0.005), while cross paths were all significantly negative (−0.235, standard error (SE) = 0.005). Consistent with a priori predictions based on developmental theory, the positive effects of achievement on self-concept and motivation in the matching domain became stronger with age. However, the critical negative effects of achievement in one academic domain on self-concept and motivation in another domain also increased across age cohorts, suggesting that with age these subject domains become more distinct. There were also substantial country differences, in which support for I/E predictions was weaker in three Middle Eastern Islamic countries compared to five Western and 4 Asian countries.

Extensions of I/E Studies: Assimilation and Contrast Effects

The majority of I/E studies have been conducted in relation to the math and verbal domains. However, the theoretical underpinning of the I/E is based on a continuum of academic domains that vary between the end points of mathematical and verbal subjects (**Figure 1**) based on a higher-order factor analysis in which lower-order ASC factors can be explained in terms of two higher-order (math and verbal) academic factors. Similarity between different academic domains in this conceptual framework is based on how close they are to each other on this underlying continuum – operationalized as correlations among the different domains that were the basis of the higher-order factor structure. There is consistent support for negative effects based on comparisons of maximally dissimilar dimensions at the end points of the academic continuum (e.g., the negative cross paths in

Figure 2), referred to as contrast effects in the broader social comparison literature (see Möller and Marsh, 2013).

The theoretical underpinning of the I/E model posits that the negative contrast effects will diminish and might even become positive assimilation effects when dimensional comparisons are based on domains that are close together on the academic continuum. Thus, for example, Möller et al. (2006) found that math achievement had a positive effect on physics self-concepts. Similarly, recent research (Parker et al., 2013) based on PISA data indicates that – consistent with the I/E model – paths leading to MSC (the only self-concept domain assessed) were positive for math achievement and negative for verbal achievement. Critically, the path from science achievement (a domain close to math on the underlying academic continuum) to MSC was also positive; science achievement was positively predictive of MSC, even after controlling for science (and verbal) achievement: an assimilation effect. However, the TIMSS I/E study (Marsh et al., 2014) tested the I/E model more fully in relation to math and science constructs (achievement, aspirations, self-concept, and positive affect in each domain); there was clear evidence of contrast rather than assimilation effects.

They had however, considered a generic science scale that ignored potentially distinct subdomains of science self-concept. Thus, for example, in their German sample, where physics was taught as a separate subject, Möller and Husemann (2006) found small positive effects of math achievement on physics self-concept and of physics achievement on MSC. We also note that contrasting contextual effects might be reinforced by the simultaneous presentation of items from only two subject domains, which could lead to an implicit demand on students to contrast themselves in relation to the two subjects. Clearly there is need for further research as to how robust the correlations are as an index of domain similarity, and the conditions under which apparently elusive assimilation effects are found.

Other researchers have focused on the generalizability of I/E effects when the focus is on two verbal domains (native language and nonnative language), typically in combination with the math domain. Although these studies (e.g., Xu et al., 2013) typically have found contrast effects (negative cross paths) from both verbal domains to MSC, the results have not been entirely consistent for the two verbal domains, suggesting that neither assimilation nor contrast effects were particularly strong.

Marsh et al. (2015) offered new predictions, theoretical insights, and methodology associated with dimensional comparison theory (DCT; Möller and Marsh, 2013) based on multiple academic domains (native language, foreign language, history, biology, physics, and math). DCT posits that the negative contrast effects based on maximally different (far) comparisons will diminish and may even become positive (assimilation) effects when dimensional comparisons are based on complementary domains that are close together on the academic continuum (near comparisons). In the first test of new DCT theoretical predictions based on such a comprehensive range of academic domains, they provided clear support for the critical prediction that paths for achievement to ASC based on near comparisons will be less negative than those based on far comparisons.

Extensions of I/E Studies: Integration with Other ASC Models

In addition to the I/E model, other theoretical models of relations between ASC and achievement have dominated recent ASC research: the reciprocal effects model (REM) and the big-fish–little-pond effect (BFLPE), described below. Although both these models have much theoretical and empirical support, they are traditionally based on responses to a single domain of academic self-concept. However, some work has been done toward integrating them with the I/E model.

Reciprocal Effects Model

Although the research reviewed here demonstrates that ASC and academic achievement are substantially correlated, a critical question is the causal ordering of these two constructs. Traditional approaches to this question took an 'either-or' approach – either achievement causes ASC (a skill-development model) or ASC causes achievement (a self-enhancement model). However, Marsh and Craven (2006) argued theoretically and empirically for a dynamic REM integrating the skill-development and self-enhancement models, in which both ASC and achievement are causes and effects of each other (see Figure 4). Support for the REM requires that both sets of paths are statistically significant, but the linkages from prior self-concept to subsequent achievement are particularly important. There now exists substantial support for the generalizability of the findings over age, nationality, different measures of self-concept and achievement (Marsh and Craven, 2006). However, of critical importance to this article, nearly all REM research is based on a single domain of ASC: typically MSC, VSC, or global ASC, while I/E studies typically are based on measures collected on a single occasion.

Based on longitudinal measures of achievement and ASC in both math and verbal domains, Möller et al. (2011) proposed the Reciprocal Internal/External frame of reference model (RI/EM), integrating the REM and I/E models. Using three waves of data, they found good support for both REM and I/E models when each was evaluated separately. Consistent with RI/EM predictions, they found positive longitudinal effects of grades and ASCs on subsequent grades and ASCs within domains, and negative effects of grades on subsequent ASCs across domains. A unique, new feature of the RI/EM is the effect on ASC in one domain on subsequent achievement in a different domain. Although these effects were also negative, the effects were small and not always statistically significant.

Big-Fish–Little-Pond Effect

Marsh (see review by Marsh et al., 2008) proposed the BFLPE to encapsulate frame of reference effects that are based on an integration of theoretical models (e.g., relative deprivation theory, social comparison theory, psychophysical judgment, social judgment). In the BFLPE model, students are hypothesized to compare their abilities with the abilities of their classmates and to use this social comparison impression as one basis for forming their own self-concept (Figure 5); individual ability is positively related to ASC (the brighter I am the higher my ASC) but school-average ability has a negative effect on ASC

Figure 4 Prototype causal-ordering model for testing self-enhancement, skill-development, and reciprocal effects models. In this full-forward, multiwave, multivariable model, multiple indicators of academic self-concept (ASC) and achievement (ACH) are collected in three successive waves (T1, T2, and T3). Each latent construct (represented by oval shape) has paths leading to all latent constructs in subsequent waves. Within each wave, ASC and ACH are assumed to be correlated; in the first wave, this correlation is a covariance between two latent constructs, and in subsequent waves, it is a covariance between residual factors. Curved lines at the top and bottom of the figure reflect correlated uniquenesses between responses to the same measured variable (represented by boxes) collected on different occasions. Paths connecting the same variable on multiple occasions reflect stability (the solid gray paths), but these coefficients typically differ from the corresponding test–retest correlations (which do not include the effects of other variables). Dashed lines reflect effects of prior ACH on subsequent self-concept, whereas solid black lines reflect the effects of prior self-concept on subsequent ACH. British Psychological Society, Leicester, UK.

(the brighter my classmates, the lower my ASC). Extensive support for the BFLPE generalizes across student groups, subject domains, ASC instruments, and cultures (see review by Marsh, 2007; Marsh et al., 2008). However, again nearly all of this research is based on a single domain of ASC: typically MSC, VSC, or global ASC.

Indeed, integration of these two theoretical models suggests that the negative BFLPE could be accompanied by a compensatory positive effect (the BFLP-CE) when both math and verbal domains are considered simultaneously. The I/E model suggests that processes that change self-concept in one domain have a compensatory effect on self-concept in another domain, leading to the predictions that: (1) school-average ability in math has a negative effect on MSC (the BFLPE) but a positive effect on VSC (the BFLP-CE); and (2) school-average verbal ability has a negative effect on VSC (BFLPE) but a positive effect on MSC. Marsh (1990) provided initial support for this integration of I/E and BFLPE models, showing that school-average math ability negatively predicted MSC but positively predicted VSC, and vice versa for English achievement. However, compensatory effects found by Marsh (1990) were small, and finding appropriate tests of the integrated BFLP-CE model has proved difficult, because school-average math and verbal achievements typically are so highly correlated (r's > 0.95) that school contexts in the two domains cannot be easily differentiated. The following suggestions by Marsh et al. (2015) capitalized on an important feature of the German educational system; some academically selective schools select students on the basis of overall achievement, but others have a subject-specific theme and select students who excel in a particular area, rather than overall. Consistent with theoretical predictions, there were BFLPEs for both types of selective schools, but the BFLP-CE, based on the I/E model, was only evident for the themed (magnet) schools.

Theoretical Extensions of the I/E Model

Denissen et al. (2007; Eccles, 2009; Parker et al., 2012) subsequently integrated the I/E model into the traditional

Figure 5 Path model predictions based on the big-fish–little-pond effect (BFLPE). Adapted with permission from Marsh, H.W., 2007. Self-concept Theory, Measurement and Research into Practice: The Role of Self-concept in Educational Psychology. British Psychological Society, Leicester, UK.

expectancy-value theory (EVT). EVT (Eccles, 2009; Eccles and Wigfield, 1995; Wigfield and Eccles, 2002) posits that expectancy (often operationalized as self-concept) and components of value (e.g., intrinsic, extrinsic, cost) predict a wide range of future outcomes. Although self-perceived competence was related to several different value constructs in the EVT model, the relations with intrinsic value and interest were consistently the strongest (Wigfield and Eccles, 2002). Whereas expectancy beliefs are closely associated with performance in both cross-sectional and longitudinal studies, interest and other value beliefs tend to be better predictors of choice, effort, and persistence at achievement-related activities (e.g., Marsh et al., 2005).

Emphasizing the link between EVT and the I/E model, Eccles (2009) argued "that both external and internal comparison processes are key – people assess their own skills by comparing their performances with those of other people and with their own performances across domains" (p. 82) and demonstrated how this internal dimensional comparison process has a critical influence on academic choice behavior (e.g., choice of university major; see Parker et al., 2012).

Pekrun and colleagues (Goetz et al., 2008; Pekrun, 2006) extended their control-value theory of achievement emotions to incorporate the I/E model. This was done to explain the extreme domain specificity of students' achievement emotions, based on their hypothesis that "the mechanisms addressed by Marsh's (1986) I/E model could operate for students' emotions as well" (Goetz et al., 2008, p. 7). They found that emotions were substantially more domain specific than achievement in different math and verbal subjects, and that enjoyment was the most domain specific emotion. Goetz et al. (2008) subsequently found support for the I/E model in relation to both self-concept and enjoyment, but showed that achievement/enjoyment relations were mediated by self-concept. Because enjoyment is a key component of intrinsic motivation, this research complements EVT studies showing the extreme domain specificity of intrinsic motivation.

Policy and Practice Implications

The I/E model also has implications for educational practice and for our understanding of self-concept formation. When asked to infer students' self-concepts, teachers, parents, and others imply that, consistent with corresponding measures of achievement, students who are bright in one area tend to be seen as having good ASCs in all areas, whereas students with lower ability in one area are seen as having poor ASCs in all areas. Similarly, teachers and parents may underestimate the domain specificity of affective variables that are influenced by ASC, such as students' academic emotions, interest, and motivation to learn. For example, teachers are likely to believe that students' enjoyment and anxiety generalize across school subjects. However, if teachers and others better understood the formation of self-concepts in different academic domains, then they would be able to understand their students better and provide more appropriate, credible feedback, particularly for less able students. Even bright students might have an average or below-average self-concept in their weakest school subjects; this may seem paradoxical, in relation to their good achievement (i.e., relative to other students but not relative to their own performance in other school subjects). Similarly, even poor students may have an average or above-average self-concept in their best school subject; this appears paradoxical in relation to their below-average achievement in that subject, but not when considered relative to their other school subjects.

This article is a revision of the previous edition article by D.J. Hogan and J.M. Pinto da Cunha, volume 11, pp. 7733–7737, © 2001, Elsevier Ltd.

Abstract

While internal migration is widely considered to be an essential driver of economic efficiency in More Developed Countries (MDCs), the process remains relatively understudied, undermeasured, and misunderstood in Less Developed Countries (LDCs). Existing evidence suggests that internal migration in LDCs, as in MDCs, is beneficial for development and social change, though the pathways of influence are complex. This article explores evidence on measurement, levels and trends, causes, and consequences of internal migration. The article situates internal migration within the broader frameworks of development and livelihoods, as both cause and consequence.

While internal migration is widely considered to be an essential driver of economic efficiency in More Developed Countries (MDCs), the process remains relatively understudied, undermeasured, and misunderstood in Less Developed Countries (LDCs). In recent years international migration from LDCs has gained increasing attention from researchers and policy makers, largely on the basis of the economic potential of the estimated $515 billion dollars in annual cross-national remittance flows (World Bank, 2014). While less lucrative per average episode, internal migration affects a far greater share of the population of many LDCs while in many cases carrying fewer costs or risks. Yet many LDC governments and development experts remain ambivalent about the role of internal migration in economic development and concerned about the potential burden of future migration related to climate change (De Haas, 2010; Bakewell, 2008). Existing evidence suggests that internal migration in LDCs, as in MDCs, is beneficial for development and social change, though the pathways of influence are complex.

The causes and consequences of migration can be broadly situated within processes of development and livelihoods (de Haas, 2006; Ellis, 1998). Migration scholars have recently rediscovered the mobility transition framework identified by Zelinsky (1971), which connects migration to the broader framework of demographic transition and modernization. The mobility transition implies a shift in both the extent and nature of migration, from circulating mobility over short distances (premodern), to increased and systematic migration to urban and frontier areas (early transition), to a slowdown in urban and frontier migration with increasing regional and interurban mobility as economic development deepends. These stages effectively illustrate the relationship between development and the well-documented 'migration hump' in which migration rises and falls over time (de Haas, 2006; Martin and Taylor, 1996). Migration is fed by the absolute underdevelopment of sending areas, yet processes of development also create incentives and resources necessary to migrate. Migration then feeds further processes of development (and in some cases underdevelopment), thereby creating conditions for new economic opportunities in sending areas, both via further migration and economic transformation of the sending area.

While a general story has begun to emerge, our knowledge of internal migration is incomplete in many ways, most notably due to the patchwork of data sources, causal frameworks, and micro–macro designs. Cross-national comparisons of the quantity of internal migration tend to come from exhaustive efforts to reconcile data from incomplete and incompatible data systems. By contrast, most evidence on the social, economic, cultural, and ecological drivers and impacts of migration come from high-quality data from geographically bounded surveillance sites that may not necessarily represent internal migration more broadly. Few studies have articulated across these divergent streams, and both approaches are bedeviled by the complexity of migration, beginning with the very definition of migration.

Measurement and Definitions

The definition and classification of migration depends primarily on spatial and temporal variables. Spatially, the identification of internal rather than international migration depends on clear delineation of national boundaries (King and Skeldon, 2010). Shifting boundaries challenge the classification of internal versus international moves. As just one example, were the approximately 15 million individuals displaced during the partition of India internal or international migrants, and does it matter whether a person moved 1 day before or 1 day after the actual partition on 14 August 1947? Distinctions are also confounded by the common though declining presence of frontier-free boundaries in which migrants may make little distinction between international and internal moves across the same economic, ecological, or cultural space (King and Skeldon, 2010).

Looking within the boundaries of a nation, the frequency and meaning of migration will depend greatly on the geographic boundaries across which migration is defined. The use of larger geographic units can allow for a clearer definition of migration, yet eliminates coverage of short-distance moves (Ravenstein, 1885).

Classification of migration is also temporal. In systems that allow the direct estimation of migration, including panel surveys and demographic registration systems, migration is

most often bounded by the definition of a 6-month absenc from the household. This definition may be further modified by accounting for functions and intentions. Many populations also experience high rates of seasonal migration, with significant consequences for well-being (Rogaly and Rafique, 2003). While such moves can be identified based on patterns of short-term employment, short-term movement may also relate to schooling, childbirth, provision of care to the disabled, and displacement.

Moves of long duration may also be qualified by migrant intentions, most notably by the practice of solo, temporary, or circular migration, as in South Africa and China. In South Africa, the Apartheid-era pattern of enforced circular migration among black populations persists 20 years after the end of Apartheid, with migrants returning home during episodes of unemployment, illness, or retirement (Clark et al., 2007). The Agincourt Health and Demographic Surveillance System, which collects data in a former homeland area of Mpumalanga Province, thus classifies temporary migrants as *de facto* members of the sending household, recording the number of months that the individual spends away from the household (Clark et al., 2007).

In practice, most societal estimates of internal migration are based not on prospective observation of migration events, as in a registration system, but instead on intercensal estimates of mobility. The International Migration Around the GlobE (IMAGE) project has conducted an exhaustive summary and compilation of available migration data from censuses and other sources, as summarized in **Table 1** (Bell et al., 2014; Bell and Charles-Edwards, 2013). They note that 142 of 193 nations surveyed included direct questions on migration. In terms of duration, these questions varied from the ideal but resource-intensive approach of measuring the duration of residence in the most recent location, thereby indicating the exact year of migration but excluding earlier moves. Other censuses report changes in residence over a fixed period, typically 1, 5, or 10 years, thereby capturing moves over a fixed observation period but excluding onward or circular moves. Most countries recorded only whether a respondent was living in a different location from their place of birth, meaning that lifetime circulation is ignored and rates of ever-migration will be sensitive to population aging. Whatever the temporal definition of migration, most censuses only track moves between the primary or secondary administrative units, thereby ignoring local moves. Intercensal estimates inherently exclude the behavior of nationals living overseas, except in systems that allow *de facto* residence. Finally, one-quarter of countries did not include any migration questions on their censuses, meaning the net migration flows can only be inferred indirectly by observing changes in population net of natural increase.

Bell and Charles-Edwards (2013) note that a significant number of countries, including 37 of the 51 that lack census-based estimates, have some survey-based migration data. Migration life history surveys can provide rich coverage of lifetime migration activity across a wider range of durations and distances, though such data are both cost intensive, they may still not offer cross-national comparability, and they may be subject to retrospective reporting bias (Reed, 2013) While IMAGE reports a number of migration-specific surveys, more widely available data sets carry significant limitations and biases. For instance the Demographic and Health Surveys (DHS), the most widely reproduced survey in Sub-Saharan Africa, only includes women of reproductive age and includes just two questions on migration. Some recent studies have begun to explore the use of mobile phone records and social media feeds to infer mobility rates, but these methods require further refinement, have limited potential for behavioral analysis, and raise ethical concerns over privacy (Blumenstock, 2012).

Table 1 Countries collecting internal migration data since 1995

Region	*Census*	*Register*	*Survey*	*Multiple sources*	*Total countries collecting data*	*Total countries*
Africa	43	0	38	31	50	54
Asia	37	15	24	27	41	47
Europe	31	32	32	34	41	43
Latin America and the Caribbean	32	0	12	12	32	33
Northern America	2	2	2	2	2	2
Oceania	13	1	2	3	13	14

Levels and Trends

No explorations of levels and trends in internal migration would be complete without a discussion of urbanization measures. **Table 2** compares urbanization rates for broad geographic regions in 1970, 1990, and 2010. Most developing regions have substantially lower levels of urbanization, even after including emerging high-income states within those regions. In the past and present, Latin America remains an outlier for its high levels of urbanization. Historically, Asia and Sub-Saharan Africa have had especially low levels of urbanization. The past 20 years have seen substantial urbanization in East Asia, which rose from 33.7% in 1990 to 51.7% in 2010, resulting primarily from high levels of mobility in China. South Asia and Sub-Saharan Africa have historically had rates of urbanization that were both low and strongly correlated with levels of economic development. In more recent years Sub-Saharan Africa has seen more rapid urbanization even as economic development has proceeded more rapidly in South Asia, raising concerns about the social and economic consequences of urbanization in Sub-Saharan

Table 2 Rates of urbanization for key world regions, 1970–2010

	Percent of population in urban areas		
Major area	1970	1990	2010
South Asia	18.7	25.0	30.6
Sub-Saharan Africa	19.3	27.9	36.0
East Asia and Pacific	24.8	33.7	51.7
Middle East and North Africa	42.8	54.8	62.6
Latin America and Caribbean	57.0	70.3	78.8
Europe and Central Asia	60.6	67.4	70.0
North America	73.8	75.4	82.0

Africa. While urbanization is more readily observed than migration flows, the convolution of internal migration and urbanization is problematic for many reasons. First, a substantial share of urbanization in all regions results not from migration, but from the administrative reclassification of areas from rural to urban (Lucas, 1997). Second, rural–urban moves have historically constituted a small share of total internal migration, particularly as internal migration systems mature and already display high urbanization rates, as in Latin America (Ravenstein, 1885; Zelinsky, 1971).

The IMAGE project has attempted to reconcile disparate temporal and spatial measures of migration flows from census data (Bell and Charles-Edwards, 2013). In one summary exercise summarized in **Table 3**, they use flows of migration across the largest administrative regions in observed countries to estimate 5-year and lifetime internal migration intensity rates for each major world region. Lifetime measures of migration intensity suggest that the experience of migration is highest among countries in Latin America (18.0%) compared with Africa (12.5%) and Asia (7.2%). While lifetime migration intensity can be estimated for a wider range of censuses, it may not reflect current trends, particularly as extended duration of survival allows past migrants to live increasingly long lives. Five-year measures of migration intensity reveal greater comparability among these three regions, with the highest levels recorded in Africa (4.6%), then Latin America (4.1%), then Asia (2.9%).

The authors use these estimates to approximate the total number of internal migrants in the world today. They estimate that 763 million, 11.7% of the world's population live outside their region of birth but within their country, including 496 million in Africa, Asia, and Latin America. Both numbers are considerably higher than the estimated 200–300 million thought to be living outside their country of birth.

Finally, they use the spatial asymmetry of interzonal migration flows to estimate a Migration Effectiveness Index (MEI), the extent to which migration actually redistributes population as opposed to merely circulating populations. They observe a relatively low MEI for most Latin American Countries in the 2000 census round (e.g., 7.2% in Chile, 14.6% in Costa Rica, 23.3% in Brazil, 28.8% in Mexico), with only Ecuador showing an MEI of 63.3%. As a result, the aggregate net migration rate (the migration intensity * MEI) is actually below 2% for most Latin American countries other than Ecuador. In Asia, by contrast, MEIs are relatively high, ranging from 62.4% in China and 59.7% in Vietnam to 26.2% in the Philippines and 19.8% in Indonesia. As a result, the net impact of migration on population distribution may be much larger in Asia. For instance, they estimate that 1.7% of China's population experienced a net shift of province of residence in the 5 year preceding the 2000 census, compared with just 0.6% net movement between Brazil's states and 1.2% between states in the USA. In Africa, where fewer countries provided 5-year rates, the pattern was suggestive of high overall net migration with more minimal impact. One counterexample would be South Africa, where a 4.3% migration intensity and 33.9% MEI resulted in a fairly substantial 1.4% net movement between provinces.

Finally, contrary to popular expectation, they found that internal migration rates in most countries declined or remained

Table 3 Global estimates of the number of internal migrants in 2005, five-year and lifetime data

stable between 1990 and 2000, especially in previously mobile Asian countries like Indonesia, Malaysia, and Vietnam. The notable exception was China, which saw the intensity of interprovincial migration more than double between 1990 and 2000 (1.1–2.7%), as did the MEI (from 32.2 to 62.4%), resulting in a fourfold increase in the rate of population redistribution from 0.4% to 1.7%. They note that census data for 2010, already available in Indonesia and Vietnam, show a marked rebound in migration intensities. In Latin America, migration intensities were mostly stable through the 1990 to 2000 period. None of the African censuses used provided sufficient data to track 5-year migration trends.

Causes of Migration

The decision to migrate can be situated within the neoclassical utility maximization frameworks employed for models of international migration. Arthur Lewis (1954) developed a two-sector model including an underdeveloped agricultural sector with surplus employment and a growing manufacturing sector that would draw excess labor from agricultural areas, increasing urban productivity. This emphasis on urban growth as a driver of migration led to the frequent reference to 'pull factors' in migration. Ranis and Fei (1961) refined the Lewis model to address the role of out-migration in reducing capital-labor ratios in the rural sector, thereby also improving rural productivity, which would give rise to the notion of 'push factors' driving people away from the rural area.

These sectoral models were further refined at the individual level. Sjaastad (1962) formulated the probability of migration between two locations in terms of the difference in expected wage between the two areas net of any financial and nonfinancial (psychic) costs of moving. This model opened the way for consideration of individual variations in human capital. In this framework, for instance, the tendency for migration to peak in early adulthood can be understood as a maximization of the long-term returns to migration over the life course.

One of the most frequently replicated drivers of migration is higher levels of human capital. Direct comparisons of the association of schooling to international versus rural–urban migration tend to find that rural–urban moves are more strongly associated with schooling. Even though international migration may be more lucrative, rural–urban migration may carry greater opportunities for professional advancement and skills acquired in local schooling systems may be more valuable in the domestic economy. To the extent that it has been studied, the association of schooling to short-distance and rural–urban moves is weaker than for rural–urban moves.

While the association of schooling to internal migration is well established, few studies have attempted to separate the specific effect of schooling from other forms of human capital like physical health, cognition, or psychosocial health. The international migration literature has now strongly established the 'healthy migrant effect' whereby migrants tended to be strongly selected on physical health, even in migration streams dominated by occupations that do not demand physical exertion. A few studies have just recently begun to test for the presence of health selection in internal migration, generally supporting the hypothesis (Lu, 2008).

Subsequent extensions of the neoclassical model moved beyond individual human capital to understand the role of familial financial capital, physical capital, and livelihoods in the migration process. The Harris-Todaro framework extended the standard model by arguing that the expected urban wage be taken as the average wage times the average probability of employment (Harris and Todaro, 1970). This allowed for explicit consideration of aversion to the risk of current or future unemployment, variations in the probability of employment due to migrant skills, and the role of exclusionary policies or trade unions in restricting actual access to employment. Mincer (1978) extended these models to the locus of a family of movers, arguing that the net benefit of migration to the working mover(s) must outweigh the cumulative costs experienced by all tied movers, thereby explaining the relatively low migration rates experienced by marriage people and the dynamics of tied mover migration.

Mincer's work, combined with a growing awareness of the phenomena of temporary, circular, and seasonal migration, shifted the focus of migration decision-making to the family, including both movers and nonmovers. The New Economics of Labor Migration, which has been the normative model of migration decision-making for almost two decades, posited that individual migration behavior is often the product of household or family decisions aimed at maximizing the welfare of a collective income-pooling unit (Stark, 1991). As a result, potential movers would consider a much broader range of potential outcomes than merely current income from migration, including long-term income from a combination of income streams of which migration was just one part. This also led to consideration of the unique nature of migration within the context of traditional rural agricultural production described by Lewis. Given weak capital markets in rural areas, families may see reliable, high-value cash transfers sent by migrants as a source of insurance against crop failure or other catastrophe and as a critical source of capital for investments in land and the means of production (Rosenzweig and Stark, 1989).

NELM offered two critical predictions that deviated from the standard neoclassical model. First, while migration may be a response to low current wages, it may also be part of an effort to protect or enhance existing income streams (Lucas and Stark, 1985). Households with greater land holdings may have less need for current income, but they may also have a greater interest in insuring production against shocks and in generating capital for economic expansion. Households may also be able to use land or revenue from land to finance migration. This is borne out by studies documenting a nonlinear relationship between land holdings and migration (VanWey, 2005). Second, community or contextual factors predisposing households to economic risk or limiting their ability to manage risk may increase the incentives to migrate, particularly among households with greater exposure to agricultural production (Rosenzweig and Stark, 1989).

The NELM framework was broadened through the more general linkage of migration to broader life course dynamics of production and consumption (de Haan, 1999; Ellis, 1998; de Sherbinin et al., 2008). While NELM described the conditions of an agricultural producing household with long-term interests in agricultural enterprise, it was less effective at describing

the conditions facing a range of households whose livelihoods were less deeply tied to agricultural production, but instead to a nexus of on-farm and off-farm labor activities in which land was a less direct driver of migration (Bilsborrow and DeLargy, 1990). On the other end of the socioeconomic distribution, declining family sizes and increasing socioeconomic aspirations may lead some families to view the migration of one or more family members as a pathway toward an eventual transition to the city, to the elevation of familial status in the sending area, or both.

As a result, the internal migration literature has shifted quite rapidly in the past decade to situate migration within a general livelihoods framework (Ellis, 1998). A recent review emphasized the role of human capital, financial capital, physical capital (e.g., land), natural capital (environmental resources and amenities), and social capital as drivers of migration (de Sherbinin et al., 2008). Critically, migration may be driven by a surplus or deficit of these forms of capitals, or more likely by a desire to leverage existing capital to either enhance or protect future livelihood opportunities. The livelihoods framework is useful not only for predicting migration in general, but also for predicting complex processes such as temporary versus permanent migration, family versus individual, and sequences of migration to multiple destinations (Bilsborrow and DeLargy, 1990).

One further advantage of the livelihoods framework lies in understanding that migration is as much a process of economic, social, and cultural reproduction as it is a process of disruptive innovation. If migration is deeply embedded in social structures, institutions, and livelihood strategies, then it may serve to reproduce and reinforce those structures. Numerous studies have demonstrated how the role of women in the process of migration at the family and community level reflects women's disadvantaged position within the household economy, lineage and inheritance systems, employment, and political institutions (Curran and Rivero-Fuentes, 2003; Gray, 2012; Mojola, 2014). While mobility has the potential to disrupt these well-worn patterns, migration may just as easily expose sending populations to new modes of discrimination imposed by the state, by employers, or by the globalizing forces that drive the need for migrant labor (Silvey and Elmhirst, 2003).

The State and Other Political Actors

Governments and nonstate institutions play a direct and indirect role in promoting or discouraging migration at the origin or destination. This is most notable in examples of the forced migration of ethnic, racial, or other status groups from origin areas (Raleigh, 2011). In many cases, states have also designated the eventual destination of internally displaced peoples (IDPs), most notably in the case of the system of Native American reservations in the United States, Jewish ghettoes in Europe, and the African homeland system under South African Apartheid. While direct displacement activities may affect entire populations without selectivity, evidence suggests that other forms of conflict-related migration may be subject to considerable selectivity in terms of livelihoods, vulnerability, and human capital (Bohra and Massey, 2012).

States may also play a direct role in internal displacement through development processes, as in the inundation of communities by hydroelectric dams (Hunter, 2005; Cernea, 2006). While some such developments may necessarily occur in a particular location (e.g., dams must be situated at a particular run of the river), states nonetheless have the opportunity to minimize the population impacts of such projects, to plan them in ways that are more conducive to population retention, and develop resettlements that meet the economic and cultural needs of the inhabitants. Relatively few studies have followed populations displaced by government projects, those that have been conducted suggest a high rate of onward migration among the displaced and anticipation of migration among the nondisplaced, with high selection on other factors relating to vulnerability (Scudder, 1993; Hwang et al., 2007).

States may also play a direct role in encouraging populations to migrate to specific areas. In the case of frontier migration, states may play a direct role in forest clearing; provide subsidies in the form of cash, land, or tools; and provide indirect support through legal institutions, public works, and military protection (Shrestha et al., 1993; Alston et al., 1995; Fearon and Laitin, 2011). The processes of settlement and displacement are uniquely linked in practice and often in ideology. Most areas referred to as frontiers contain indigenous human populations whose livelihoods are typically well adapted to the presettlement ecology and economy and not well adapted to the postsettlement context (Fearon and Laitin, 2011). Furthermore, settlement programs, particularly direct financial incentives, may be targeted directly toward one ethnic group and may directly or indirectly deprive other groups of access to resources, whether by intent or practice (Yiftachel and Ghanem, 2004). As a result, settlements can have adverse consequences on native and migrant populations, with frequent informal and formal conflict among the groups. The often-harsh conditions and weak institutions of frontier areas can lead to high levels of return migration and second-generation out-migration among settlers, again with significant selectivity on individual and household characteristics (Parker et al., 2008; VanWey et al., 2012).

States also exert considerable control over internal migration through legal and economic policies, through direct restrictions on mobility and through the management of policies relating to entitlements, urbanization, and land reform. A few nations have legal systems that directly control the flow of migration. The South African Apartheid labor policy was managed by a system of passes restricting migrants from settling, bringing family, or moving freely in designated white-only areas, thereby recreating the most severe disadvantages inherent in an international guest worker system in a domestic context (Wolpe, 1975). More recently, China's *hukou* system, in which an individual's *de facto* residence and access to social entitlements is assigned at birth, has similarly depressed the wages, bargaining power, and entitlement access of rural–urban migrants (Mackenzie, 2002). Restrictions on urban residency may also reduce wages by forcing solo and temporary migration, thereby shifting the costs of reproduction, retirement, and unemployment to the rural area, where smallholders may subsist through a combination of agricultural and migrant earnings. By contrast, development policies in post-WWII Latin America focused on the enclosure of lands and the promotion of high-wage, high-benefit jobs, thus encouraging permanent

migration, whether into formal employment and housing or to informal employment in informal settlements (de Janvry and Garramon, 1977). This variation may go some way to explaining the distinct patterns of urbanization in Latin America and Asia.

Public service provision at the source or destination may also alter migration flows, though in unpredictable ways. The United States and European Union have a substantial literature on the 'welfare magnet hypothesis', whereby differential provision of public transfers or services will make some areas more attractive, particularly for low-skilled populations (McKinnish, 2005). These studies have now been replicated in LDC contexts, with inconsistent results. Studies of cash transfer programs have identified attenuated or positive effects on migration, potentially due to the diversification of income streams or the availability of moving costs (Ardington et al., 2009). A study of programmatic placement of valuable health services in the Matlab area of Bangladesh, on the other hand, finds negative effects on out-migration, presumably due to the amenity value of living in the service area (Barham and Kuhn, forthcoming). A long-term study of an array of public services in Nepal found a short-term amenity effects on reducing migration and a long-term human capital effect on increased migration (Massey et al., 2009). Taken together, the evidence suggests that the role of the state in driving migration is both substantial yet mediated heavily by migration context and individual livelihoods.

Environmental Factors

More extensive research has been conducted on the role of environmental resources in determining migration (Hunter, 1998). This is understandable given the potential relationships between environmental change and modes of agricultural production that continue to support rural livelihoods (Parker et al., 2008). New patterns of environmental change at global and local scale add further urgency to such research (Bardsley and Hugo, 2010). While changes in the ecosystem services provided by a local environment can theoretically reduce incentives to migrate, most research has thus far focused on the role of the environment in driving migration, primarily as a push factor that reduces the value of the ecosystem (Gray, 2009). Conversely, most research on receiving areas has focused on the value of ecosystem services, for instance in coastal areas, as a pull to migration, and on the consequences of in-migrants for those ecosystems (Hunter, 1998; Curran, 2002).

The literature on environmental determinants of out-migration highlight the need to distinguish direct pathways of environmental risk – for instance those relating to natural hazards – from those effects that are mediated by livelihoods (Hunter, 2005). The direct pathway has been subject to considerably greater attention from policy makers and media due to the perceived risk of future climate-induced migration (Bardsley and Hugo, 2010). A number of studies have estimated that between 10 million and 40 million people are already environmental refugees, and that this number could approach 200 million by the year 2050, yet critics have questioned the definition of environmental refugee used in these studies (Gemenne, 2011).

One indication of a truly distinct process of environmental displacement would be the absence of individual- and household-level selection in the decision to migrate. If people are truly compelled to move, then there would be no place for individual agency, yet few cases of environmental migration meet this test. One of the few large-scale studies of such a disaster linked satellite data on tsunami to data on household migration behaviors in posttsunami Aceh, Indonesia (Gray et al., 2014). While the study found that individual and household selectivity in migration was much lower in more heavily damaged areas, these distinctions nevertheless existed on a continuum. Even moderately affected areas showed considerably selectivity. Even in heavily damaged areas, factors like poverty and female headship determined whether a household migrated to a displacement camp or to the home of a relative, and whether the displaced eventually returned. Hunter (2005) notes that responses to natural hazards, particularly chronic exposures like environmental contamination, tend to exist on a continuum of coping responses, including remaining in place, moving short distances, having some family members move, or total displacement, though even the displaced may return. Finally, perception of the risk of natural hazard precedes the occurrence of actual catastrophes by many years, so that far more households in risk-prone areas will use migration as part of a long-term risk management strategy to diversify livelihoods and even ensure a place of refuge in case of future disaster (Bardsley and Hugo, 2010; Hwang et al., 2007).

There is thus an emerging consensus around the notion that changing environmental conditions affect migration through a dynamic and unfolding process of livelihood depletion, livelihood risk, and perception of future catastrophic risk. While findings vary, this literature has formed a consensus around a few key findings. First, environmental factors play a more significant role in shorter distance moves than in long-distance moves, particularly overseas migration (Gray, 2009; Massey et al., 2010). Second, migration effects are more significant in the presence of measurable income shocks (for instance due to declining agricultural yields) or observable risks to livelihoods (such as drought) rather than the presence of transitory risks like flooding (Mueller et al., 2014). Third, the relationship between environmental resources and out-migration is not always negative. Environmental resources can also be framed as a source of natural capital enabling migration (Gray, 2009). Conversely, studies in the Sahel have identified conditions in which the level of environmental depletion and poverty is sufficiently acute to reduce the likelihood of migration (Findley, 1994). Finally, as with the role of the state, the environmental effects of migration are heavily mediated by community, household, and individual-level factors.

Social Capital

The practice and persistence of migration is driven in part by the accumulation of social capital, represented by knowledge, social connections, and direct opportunities to migrate through the use of social connections, often referred to as chain migration. This relationship is typically represented through the association between higher levels of past migration and

higher levels of subsequent migration at the household, community, regional, and national level (Lindstrom and Lauster, 2001; Van der Gaag and Van Wissen, 2002). Early movers tend to come from the highest strata of a community, as household wealth may buffer prospective migrants against the costs and risks associated with moving (Kuhn, 2003). As a result, some evidence suggests that migration can widen community inequalities in the short run but narrow them in the long run as opportunities diffuse more widely (Taylor and Wyatt, 1996).

Over time, some social and cultural changes engendered by migration may transcend the pathways of specific social networks and penetrate the community at large through the formation of infrastructure, institutions, values, or identities salient to the practice of migration and thus approximating an externality favoring the practice of migration (Zhao, 2003). This process of cumulative causation may include the reorientation of local markets, schooling, transport, or other infrastructure toward reducing the costs and risks of migration, changes driven in part by the expenditure of migrant remittances (Lindstrom and Lauster, 2001). As the number of individuals in a local area network having knowledge, experience, or authority in a specific destination area increases and reaches a critical density, individual social connections can be converted into a form of migration-specific social capital based on shared community or ethnic origins (Hagan and Ebaugh, 2003; Kuhn, 2003).

The notion of migration-specific social capital as a public good comes with several caveats and concerns over simplifying social capital as a public good (Portes, 1998). First, while migration opportunities may permeate some communities, the earliest opportunities may nonetheless carry the highest returns. Second, migration-specific social capital may exclude some segments of a population and reproduce existing social cleavages. A number of studies have identified the presence of separate migrant networks reflecting existing social cleavages, most notably separate networks promoting women's and men's migration (Curran and Rivero-Fuentes, 2003; Silvey and Elmhirst, 2003). Third, the distribution of a particular and potentially lucrative opportunity such as migration may carry considerable reciprocity costs that may exclude others (Burt, 2000; Winters et al., 2002). Finally, migration opportunities may often transmit through weak ties that cross community boundaries, potentially bypassing some members of a high out-migration community in favor of new entrants from other communities (Kuhn, 2003). As a result, consideration of migration impacts must take careful note of migrant selectivity and impacts on nonmigrant populations.

Impacts of Migration

Most studies consider separately the welfare of migrants themselves and those left-behind by migration. Theories of migration as a family livelihood response point to the conceptual and empirical challenge of making this distinction. Migration will typically lead to a substantial increase in the wages of the migrant, though not in all cases (Lucas, 2004). Yet a substantial proportion of migrants remit a large share of their income back to an origin household that represents a source of shared livelihood and well-being for the migrant as well. As a result, studies of migrant consumption for instance are naturally biased by the decision among many migrants to minimize consumption in the destination area specifically to maximize sending-area consumption. This decision itself has implications for the well-being and health of migrants themselves. Many internal migrants, particularly to cities, live in conditions of deprivation relative to existing urban residents, occupying low-paid and often risky jobs and living in poor living conditions, including informal settlements.

This is especially evident in the case of health, where occupational exposures, lack of access to health services, avoidance of health expenditures can interact to produce adverse health outcomes compared with urban natives and to those left behind in rural areas (Ebrahim et al., 2010). Notable concern has been expressed about the role of migration as a risk factor for sexually transmitted disease, including HIV/AIDS, though studies have lent only qualified support to the significance of this relationship among certain migration streams (e.g., short distance moves), mobility patterns (e.g., truck driving), and stages in the migration process (Deane et al., 2010). Moreover, while the tendency to reduce destination-area expenditures may carry health risks, at least one study has noted an association between the sending of remittances and increased subjective well-being of respondents in China (Knight, 2010).

The traditional focus of migration impact studies has been on the sending household and, to a lesser extent, the sending community. These studies tend to focus first on remittances from internal migrants to the sending household. There is no available global estimate of the total flow of internal migrant remittances, given the difficulty of measuring internal migration itself and the informality of many domestic remittances. Nevertheless, evidence from Asia, especially China, suggests that total domestic remittances flows are at least on the same scale as international remittances, if not as lucrative in the absolute. International migrant remittances tend to be large on a per-migrant basis, yet much of this gap is offset by the greater proportion of households that send internal migrants. Evidence from China, India, and Ghana places the total value of domestic remittances at 20–100% greater than international remittances (Castaldo et al., 2012).

Although remittances can be quite lucrative for those who receive them, the literature also highlights the selectivity of remittance flows. In addition to the notable forces of selection into migration, research also suggests selectivity in the tendency to receive remittances. Some of this selectivity is beneficial to sending households, for instance the tendency for remittances to rise during negative economic shocks (Rosenzweig and Stark, 1989). Remittances are also more likely when a migrant expects to inherit property, resulting for instance in larger remittance receipts for households with greater land holdings.

Studies of migrant and remittance impacts on sending communities generally support the presence of positive impacts, though these impacts may depend greatly on the outcome of interest, the context of migration, the social position of those impacted, migrant tenure and position, and the role of self-selection (Mendola, 2008). In general, migration and remittances result in increased consumption and the

reduction of poverty at the household level (Quisumbing and McNivel, 2010). While early studies questioned the impact of remittances on productive investments given persistent structural constraints in sending areas, some recent studies identify cases and conditions under which migration may lead to productive and forward-looking agricultural investments (Taylor et al., 2003; VanWey et al., 2012).

There is much stronger evidence to support investment of migrant remittances in human capital. A number of studies have measured positive consequences of migration for schooling investments and educational outcomes among children in migrant households and among nonmigrant children in migrant-sending communities (Quisumbing and McNivel, 2010; Kuhn, 2006).

Evidence on health outcomes among the left-behind generally point to improvements, though this depends on the outcome of interest and the social position of the beneficiary. Studies of adult self-rated health (SRH), observed physical function, mortality, and health-seeking behavior have found a positive associations with migration (Kuhn, 2005; Kuhn et al., 2011; Adhikari et al., 2011). Kuhn et al. (2011) use data from three rounds of the Indonesian Family Life Survey and a propensity matching framework to address the longitudinal effects of children's internal migration on changes in SRH, observed physical function, and mortality after accounting for self-selection into migration, though impacts were larger for high-propensity households. Some studies of adult mental health have observed negative association with migration (Adhikari et al., 2011; Arenas and Yahirun, 2011), though other studies have found a positive association (Abas et al., 2009), suggesting that the economic returns to children's migration may not fully offset the loss of personal social support.

Although there is some evidence of higher HIV/AIDS risk among migrants themselves, studies of elevated HIV/AIDS risk among the left-behind have proven far less conclusive (Deane et al., 2010). Instead research suggests that any association between mobility and HIV depends on the frequency of travel, as in the case of truck drivers or fishermen (Mojola, 2014). The association between migration and HIV/AIDS in sending communities is further confounded by the tendency for sick migrants to 'return home to die', thereby creating a spurious association between HIV/AIDS and nonmigrants living in a community (Clark et al., 2007).

Finally, a growing literature has addressed the ecological consequences of migration for rural areas, including migrant-receiving areas in cities, coastal ecosystems, and frontiers along with a few studies of migrant-sending areas. Studies of frontier areas tend to highlight the association of migration with deforestation and reduced biodiversity (Carr, 2009). Coastal ecosystem studies highlight the potential role of migration on ecosystem degradation, both through increased population and through poor stewardship on the part of migrants, but numerous case studies and systematic reviews argue that these effects depend greatly on the nature of migrant selectivity, the conditions of migration, and migrant social networks (Cassels et al., 2005; Curran, 2002; de Sherbinin et al., 2008). Studies of migrant-sending areas have identified by an agricultural deintensification effects stemming from reduced population pressure (Qin, 2010) and an agricultural intensification effect resulting from the use of remittances for mechanized agriculture, fertilizer and pesticide use, and monoculture (de Haas 2006; Gray, 2009). While the tendency for migration to increase agricultural intensity raises ecological concerns, more recent studies have noted that over the household life cycle migration may promote less ecologically demanding land uses like perennial crops and forestry (VanWey et al., 2012).

The Way Forward

Recent progress in understanding the causes and consequences of internal migration has allowed researchers to test a wide range of significant hypotheses in relation to an increasingly widely shared livelihoods framework. The inherent challenge of understanding migration as both a cause and consequence of systems of political, social, ecological and economic change requires a range of new approaches. While econometric adjustments to account for selection and community-level variation are important in establishing a causal framework for controlled impact evaluation, they also tend to obscure the truly unique aspects of migration relating to the unfolding process of reciprocal change and the variations in this process between even highly localized communities. Such reduced-form analyses must increasingly be complemented by the application of methods that explicitly address dynamic processes of change, including both qualitative narratives of change and quantitative approaches to modeling multiple interacting processes. This is particularly important in studies of migration, livelihoods, and the environment, where actual, perceived, or anticipated changes of even a relatively small scale can result in a cascade of livelihood adaptations that may be stabilizing or destabilizing (Gutmann, 2000). On the qualitative side, Mojola's (2014) recent study of local mobility, livelihoods, and gender in a wetland ecosystem in rural Kenya illustrates the possibility of weaving small but complex changes into a systemwide narrative of significant change. On the quantitative side, approaches like agent-based modeling offer the potential to quantify the consequences of migration in highly complex systems (Parker et al., 2008).

Of course complex models are only as good as their specifications, and there remain many understudied or emerging topics in migration research that require more substantial reduced-form analysis. A few topics merit special consideration. First, while numerous studies have modeled the effects of public goods on migration, few have modeled the effects of migration on the creation of public goods, particularly on the use of remittances in driving the creation of such resources. Second, most existing studies of migration and development have focused on case study areas of modest size, typically covering at most 200 000 residents. Further research must leverage novel data sources to test the hypotheses emerging at the local scale at higher levels of analysis, and perhaps conduct analysis of the impact of migration on linked ecosystems, for instance linking a rural area to an urban or frontier destination. Finally, the rise of broadband mobile communication technologies may fundamentally alter the migration process, increasing the availability to migration-specific social capital and enabling the maintenance of social relationships over long distances while also potentially reducing the need to migrate by

increasing productivity in the agricultural sector and creating opportunities to connect to global economic opportunities without physically moving. History shows that the emergence of new globalizing technologies like mobile communications will not eliminate internal migration, but merely alter its structure and function and new and previously unimaginable ways.

Internal Migration in Industrialized Countries

Michael J Greenwood, University of Colorado, Boulder, CO, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Internal migration is defined and distinguished as to its causes and consequences. Most migration research deals with causes. Migration rates are compared across industrialized countries (with Australia, Canada, New Zealand, and the United States shown to have high rates, but with US rates that have declined considerably in recent years), and various migration patterns are described, especially with respect to age and education. Migration rates are shown to fall with age after the early twenties and to rise sharply with education. Different theoretical perspectives on migration are discussed (namely, the disequilibrium and the equilibrium perspective). Moreover, various theories of migration are noted, with the human capital model singled out for special attention. Empirical findings consistent and inconsistent with this model are discussed. Several pressing questions regarding internal migration are offered, and the state of knowledge regarding the answers to these questions is discussed. The article concludes with a discussion of internal migration policies in Europe and in the United States and notes some critical issues concerning these policies.

Residential mobility and migration are pervasive facts of life in most industrialized countries, where migration is a major mechanism through which labor resources are redistributed geographically in response to changing economic and demographic forces. The migration literature may be classified into two areas of research, one dealing with the *determinants* and the other with the *consequences* of migration. Some studies treat both the determinants and consequences within the same framework. Migration research is strongly oriented toward the former.

The *determinants* of migration are the factors that affect migration, including characteristics of both places and persons and their families. This term refers to the qualitative and the quantitative importance of each factor. Place characteristics are specific to a given area, such as employment and wage opportunities, the presence of family and friends, and location-specific amenities. Personal and family characteristics help shape individual and family responses to opportunities that may exist at different locations. The *consequences* of migration refer both to the performance of migrants in their new locations relative to a benchmark (their presumed performance in their former place) and to the impacts that migrants have on others in sending and receiving areas. Traditionally, research has addressed several questions:

1. How many and who migrates?
2. Why do these people migrate?
3. Where are the migrants coming from and where are they going?
4. When do they migrate?
5. What consequences result from migration?

Many studies have aimed primarily at describing migration.

What Is Migration?

The United Nations manual, *Methods of Measuring Internal Migration* (1970), has served as the basis for several definitions of migration and migrants. It proposes the following (p. 2):

> A migration is defined as a move from one migration-defining area to another (or a move of some specified minimum distance) that was made during a given migration interval and that involved a change of residence. A migrant is a person who has changed his usual place of residence from one migration-defining area to another (or who moved some specified minimum distance) at least once during the migration interval.

Comparing Internal Migration Rates in Industrialized Countries

In most countries, people migrate from one place to another in pursuit of increased utility resulting from better employment opportunities, higher wages, and many other factors, but international comparisons of internal migration rates are difficult to make for several reasons.

Various countries define migrants differently in terms of whose movement is being considered, the type of border they must cross, and the interval over which the movement occurs. The method of measuring migration differs widely. In some countries, censuses are the main source of information concerning migration, whereas in others, population registers and other types of administrative records are the major source. The size and shape of the spatial areas between which migration is measured are not uniform either within or between countries.

Migration propensities are sensitive to national economic and demographic conditions, and consequently interregional migration propensities could differ for behavioral reasons.

The most unambiguous method of making cross-national comparisons is to focus on residential moves, but residential mobility includes more than what is commonly regarded as migration. Nevertheless, such measures suggest that rates of mobility vary widely across industrialized countries. Movement rates are high for Australia, Canada, New Zealand, and the United States. A second group of industrialized countries that is far behind these four includes France, the UK, Israel, Japan, Sweden, and Switzerland. Belgium, Ireland, and The Netherlands have the lowest rates of residential mobility.

The Determinants and Consequences of Migration – Overview

Migration Patterns

Many factors contribute to the decision to migrate. Differential characteristics of sending and receiving regions provide a potential incentive for moving, and individual and/or family traits help condition the responses to utility differentials that may arise from these different characteristics. An individual's personal characteristics – including accumulated job skills, general labor market conditions, and employment composition – will help determine the probability of gaining employment during a period of job search. Conditions in land and housing markets also may be important, and state and local taxes and the associated availability of public goods may be critical for certain potential migrants.

A number of life cycle considerations – such as marriage, divorce, completion of schooling, entry into the labor force, start of a career, birth, aging, leaving home of children, home ownership, and retirement – are critical in an individual's or a family's decision to migrate. Other personal circumstances, often related to the life cycle, are also important, such as employment status, earnings, education, accumulated skills, age, job tenure, sex, and health.

One of the most universal mobility relationships is that between age and migration. Migration propensities peak during the early to mid-20s and then decline steadily, with a slight upturn at retirement age in some countries. For example, in the United States, during the 1980s, a person aged 25–29 with 4 years of college education was over twice as likely to make an interstate move as his or her counterpart aged 35–44; over three times more likely to make such a move than someone with comparable education aged 45–64; and over three times more likely to make such a move than a peer in age who had less than 8 years of education.

Studies of the determinants of migration commonly have been formulated in the context of individual utility maximization, with some attention given to the family or the household as the decision-making unit. Models based upon such behavioral foundations have frequently been estimated with aggregate data relating both to migrants and to the determinants of migration. Before the general availability of micro- and longitudinal data, virtually all applied migration research was of necessity based on aggregate data. Although aggregate data were and are limiting in many respects, they did not prevent a boom in migration research during the 1960s and 1970s. Even in the presence of many microdata sets, aggregate data are frequently studied today. Not only are aggregate trends and tendencies of interest is their own right, but for many countries, such aggregate data are all that is available.

During the 1960s, the main thrust of migration research began to take on a more formal tone. Most of the research was not formal in a theoretical sense, but rather intuitively generated hypotheses at first were tested formally in an econometric sense with aggregate data, typically but not always with place-to-place migration data. Such models were frequently specified in the context of modified gravity models. The models are 'gravity type' in that migration is hypothesized to be directly related to the size of relevant origin and destination populations, and inversely related to distance. The models are 'modified' in the sense that the variables of the basic gravity model are given behavioral content, and additional variables that are expected to influence migration are included in the estimated relationship. These studies showed clearly that migration diminishes rapidly with increased distance and that migration is greater between more populous regions; but, migration did not always appear to be from low- to high-wage regions, nor from those with high unemployment rates to those with low rates.

Theoretical Perspectives on Migration

In almost all migration research conducted by economists prior to the late 1970s, the theoretical perspective taken was that of a disequilibrium system. The perspective is called 'disequilibrium,' because migration is assumed to be driven by the existence of a set of nonmarket clearing regional wages. Spatial variations in wages or earnings are assumed to reflect opportunities for utility gains. During more recent years, this disequilibrium perspective has been challenged by proponents of the equilibrium hypothesis, which assumes that spatial variations in wages are compensating and therefore do not reflect opportunities for utility gains.

According to the human capital approach, the potential migrant will select the locality at which the real value of the expected net benefit that accrues to him from migration is greatest. The income that the individual expects to earn at each alternative destination enters importantly into his judgment concerning the benefits associated with each location. The relevant income measure for the individual to consider is the present discounted value of his expected future stream of net pecuniary returns.

Due, in part, to the fairly consistent tendency for empirical studies based on aggregate data to fail to confirm the importance of wages or income in migration decisions, the equilibrium approach has been offered as an alternative to the traditional disequilibrium perspective described above. The equilibrium theorists begin by assuming that households and firms are in proximate equilibrium at any point in time. This assumption means that the marginal household and firm, while maximizing utility and profit, respectively, are spatially arrayed so as to receive zero consumer and producer surplus from their location. Thus, any movement from the general equilibrium configuration cannot improve utility or profit.

According to the equilibrium approach, changes in life cycle factors or generally rising real incomes continuously change the demand for consumer amenities. Because amenities are not evenly distributed spatially, migration occurs and quickly reequilibrates households. Net in-migration to amenity-rich areas tends to drive down wages and drive up the prices of locally produced goods and services and land. In amenity-poor areas, opposite patterns of change occur. Wages and local prices diverge across regions until they just compensate households for the differing amenity bundles that the various regions supply.

Family ties result in negative personal externalities that are usually internalized by the family and thus tend to discourage migration. "Tied persons" in the family are "those whose gains from migration are (in absolute value) dominated by gains (or losses) of the spouse" (Mincer, 1978: p. 753). Presuming that

their joint net returns on migrating from *i* to *j* exceed their joint net costs of migrating, a couple would presumably migrate from *i* to *j*. If, for example, the wife's expected earnings in *j* were less than in *i*, but the husband's were sufficiently greater in *j* than in *i* to offset these losses, the wife would be a 'tied mover.' On the other hand, if the husband's earnings gain in *j* were to fail to offset his wife's earnings loss in *i*, the couple would remain in *i*, and the husband would be a 'tied stayer.' Moreover, according to Mincer, such ties tend to reduce the employment and earnings of those wives who do migrate and to increase the employment and earnings of their husbands. Mincer goes on to show that increased labor force participation rates of women cause an increase in migration ties, which results in both less migration and more marital instability. Increased marital instability in turn encourages migration as well as increased women's labor force participation.

Consequences of Migration

The consequences of migration have been addressed at two levels. The first deals with the migrants themselves, where the emphasis has been on the benefits to migrating, often measured in terms of earnings gains. The second deals with migration's impact on others in the origin and the destination. Do migrants depress local wages in receiving areas and displace local residents from jobs? To the extent that migrants tend to be young and well educated, does migration deprive source regions of critically needed human capital that ensures these regions of long periods of economic stagnation?

Conclusions

Pressing Questions

Who migrates? Why do they migrate? Where do the migrants come from and where do they go? When do they migrate? What consequences does migration have for the migrants themselves and others in origin and destination regions? During the last 30 years, firm answers have been provided to many of these questions, but at the same time new, narrower, and in certain ways more refined, interesting, and certainly more challenging questions have arisen.

Migration propensities appear to vary considerably across industrialized countries for reasons that are not always obvious. Moreover, estimated parameters that address the questions raised above, while generally in qualitative agreement, are quantitatively somewhat different across industrialized countries, even when the models and data are roughly comparable. With regard to internal migration, rigorous cross-national studies are virtually nonexistent, but differences in geographic size (and hence spatial distribution of economic opportunities) and culture are likely to importantly underlie observed differences.

The Human Capital Model

Until about 20 years ago, aggregate data were used almost exclusively to study various migration phenomena. Such data embody a number of shortcomings that prevented the study of many important issues bearing on migration. The relatively recent availability of micro- and longitudinal data has had a major impact on four areas of migration research.

1. Such data have gone far toward clearing up earlier puzzles concerning the relationship between unemployment and migration.
2. They have allowed the human capital model to be tested in the migration context by allowing the estimation of migrant earnings equations.
3. They have permitted a clarification of the relationship between personal characteristics and the decision to migrate, and they have allowed a deeper understanding of the relationship between various life cycle and familial factors and migration.
4. They have permitted a detailed focus on different types of migrants, particularly primary, return, and other repeat migrants.

Researchers now know that local unemployment in the United States has a significant influence on the migration decisions of the unemployed and those who are seeking new jobs, but has little influence on individuals who are secure in their jobs. However, they do not know why this relationship fails to hold for European countries. Moreover, they do not know with great confidence why some unemployed individuals are quicker to migrate than others. To some extent, immediate migration could be discouraged if a person's spouse remains employed. What characteristics of a spouse's employment discourage migration? To what extent does it matter whether the party remaining employed is the husband or the wife? What role does the availability of unemployment insurance play in discouraging immediate migration? Institutional settings differ substantially by country, such as in the nature of unemployment insurance programs, and could cause differences in the response to personal unemployment.

The human capital model has provided a powerful analytical tool for the study of numerous important issues. It is somewhat surprising that this model has not typically provided a comparably powerful explanation of internal migration. Whether migrants are compared to otherwise comparable individuals in the origin or the destination, they appear to suffer earnings losses for at least several years after migration. This finding has been verified repeatedly for the United States and for other countries. Although several explanations have been offered for these findings, we still do not know enough about why they occur. The most likely explanation for the apparent failure of the human capital model is that the model has not failed, but rather it has just not been properly or fully implemented.

Life Cycle Impacts on Migration

The influences of life cycle changes on migration decisions have only barely been touched by researchers. The relationships between many such changes and migration, therefore, have remained undiscovered. Completion of education; birth and aging of children and the anticipation of these events; changing marital status and especially divorce; death of a spouse; acquisition of a home; retirement – these are only a few potentially important life cycle changes that are likely to importantly affect migration in industrialized countries and about which much remains to be learned.

Little is known about the interactions between migration and fertility in the contemporary United States or in other industrialized countries. A sizable literature on this topic began developing in the 1930s, but was mainly focused on rural to urban migration. A good deal of more recent work has also focused on rural to urban migrants in less developed nations, and a few studies concentrate on immigrants to the United States. However, in spite of the availability of more and better data in recent years, little has been done to study how the act of migration affects fertility in the United States or in other industrialized countries.

Migration Policies

Migration serves an equilibrating function in the economy, expediting the balancing of demand and supply forces within and across regions, and thus facilitating the operation of market economies. This facilitating role of migration has attracted the attention of policy makers. In a number of European countries, such as the UK, France, and The Netherlands, migration policy has been tied directly to regional development policy; in others, such as Sweden, migration policy has been oriented toward improving the efficiency of the labor market. In either case, a major objective has been to reduce unemployment. Subsidization of relocation expenses and employment information exchanges are the most common forms that migration policy has taken in Europe.

In the United States, policy concerns regarding migration generally are passive, although this was not the case during the nineteenth century. These concerns have been directed toward both how various national, state, and local policies have affected in- or out-migration and how migration has affected the public sector of states and localities. One policy concern that has arisen in this respect is whether the jobs created by economic development efforts go to previous residents or inward migrants.

Abstract

After defining internal reconstruction as the method of establishing earlier, unattested forms of languages without reference to 'external,' especially comparative, evidence, and sketching the history and development of the method, the article identifies a number of related but distinct procedures which fall under this heading: historical morphophonemics, regularization of systems, and universal and typological reconstruction. Each of these is explained and exemplified in turn. Historical morphophonemics involves identifying alternations between grammatically or lexically equivalent forms, resulting from phonological changes in different contexts, and reducing them to a single form, thus reversing the changes. Regularization of systems is based on the same principle in so far as it attempts to reverse changes by eliminating anomalies, but it extends this principle to cover whole systems. Universal and typological reconstruction works backward by invoking known or assumed general processes of linguistic change. The criteria for reconstruction here may be either universal or typological, the former relying on universal characteristics of language or of language change, the latter on the observation that languages fall into a number of more or less distinct types, characterized by co-occurring features. In the latter case reconstruction is effected by restoring the assumed typological consistency of the earlier language. The justification for the different procedures is discussed, and their effectiveness and reliability evaluated.

Internal reconstruction is a method for establishing earlier, unattested forms of languages without reference to 'external,' especially comparative, evidence from other languages. In this it differs from the comparative method (*see* Comparative Method in Linguistics), which is based on such evidence, though the aims of both methods are in practice the same. To signal the difference, forms or languages reconstructed by internal reconstruction are designated 'pre-forms,' 'pre-languages,' etc., as opposed to the 'proto-forms' and 'proto-languages' reconstructed by the comparative method. The method can be applied to individual languages in cases where comparative evidence is not available, for example to isolated languages or to reconstructed proto-languages.

Internal reconstruction is an extremely powerful method, and for this reason some of its results can be both speculative and controversial, though a number of the reconstructions arrived at by this method which were earlier deemed too hypothetical have subsequently become accepted, for example the postulation of a set of 'laryngeal' consonants for Indo-European (the 'laryngeal theory'), whose existence was corroborated following the discovery of Hittite (Lindeman, 1987). As in the case of the comparative method, it evolved in practice before it was formally recognized. However, since the method rests on a quite sophisticated formal analysis of language, it did not appear until the late nineteenth century, much later than the comparative method. In a youthful work, for instance, Saussure used aspects of what would now be regarded as internal reconstruction in his study of the Indo-European vowels. However, the method was not firmly established until the 1940s, principally in the work of American structuralist linguists such as Henry Hoenigswald.

Internal reconstruction is not a single, unitary method; the term embraces a number of related but distinct procedures, which we may designate as follows:

1. historical morphophonemics;
2. regularization of systems; and
3. universal and typological reconstruction.

All of these have in common the attempt to work backward in time by reversing changes that are assumed to have taken place in the language in question, but they differ in scope and in the factors that are taken into account.

Historical Morphophonemics

This is the most limited of the methods of internal reconstruction. It applies only to the reconstruction of phonology, and works by identifying phonological alternations between grammatically or lexically related forms resulting from the differential operation of phonological changes in different linguistic contexts. By eliminating these alternations and reducing the set of alternants to a single form, it effectively reverses the changes and establishes the form that existed prior to their taking effect. In practice, it is equivalent to the synchronic process of establishing 'morpho- phonemes,' or the 'underlying forms' of classical Generative Phonology (*see* Phonology; Morphophonology) – abstract phonological entities from which the occurring forms can be derived – though it interprets these morphophonemes as historical antecedents.

Consider, for example, the Latin forms given in eqn [1].

Nominative	Genitive	
consul	consulis	('consul')
genus	generis	('kind')
corpus	corporis	('body')

[1]

As we see from *consul*, the genitive is formed by adding the affix *-is* to the stem of the word, but in the case of *genus* and *corpus* the final consonant of the stem is *-s* in the nominative and *-r* in the genitive. In synchronic phonology we might regard these two sounds as realizations of the same element, a 'morphophoneme' which appears as /s/ at the end of the word and as /r/ between vowels. But the alternation can also be

interpreted historically, if we assume that this morphophoneme was actually an original phoneme, assumed to be /s/, which was changed to /r/ between vowels. We can therefore postulate earlier forms of the genitive: **genesis* and **corposis*.

This method works, therefore, by attempting to undo the effects of the splitting of phonemes in different contexts. Here, the original phoneme /s/ split into two separate phonemes, /s/ and /r/, depending on the context in which it occurred. This split resulted in a synchronic alternation between the phonemes /s/ and /r/ in different forms of the word. By identifying such alternations, and deriving the alternating phonemes from a single source, we reconstruct the earlier form of the words.

Regularization of Systems

Like historical morphophonemics, this method attempts to reverse changes by eliminating anomalies, but it extends this principle to cover whole systems of linguistic elements.

Consider, for example, the so-called 'strong' verbs of the Germanic languages. These verbs form their principal parts not by the addition of affixes (*walk-walked*; *love-loved*, etc.), but by modifying the vowel of the stem (*sing-sang-sung*; *ride-rode-ridden*, etc.). Strong verbs fall into a number of classes, according to the pattern of alternation of the vowels; only the first three are relevant here. For these verbs, we can identify three stems, whose vowels can be reconstructed by means of the comparative method, for the Germanic languages as a whole: as in eqn [2].

ClassI	*i* :	*ai*	*i*	
ClassII	*iu*	*au*	*u*	[2]
ClassIII	*i*/*e*	*a*	*u*	

It can be seen that there is a certain regularity here, though also some anomalies. By the simple expedient of regarding the *i*: of the first stem of Class I (the colon indicates length) as *ii*, the first two classes become entirely parallel, with the vowel pattern *i–a–zero*, where the vowel is followed by *i* in Class I and *u* in Class II; in the third stem, the *i* or *u* is left as the only vowel. In Class III verbs, the vowel is followed by a nasal or liquid consonant (*r* or *l*), and the *i*/*e* alternation in the first stem depends on the following consonant: *i* occurs before a nasal and *e* before other consonants. We can therefore eliminate this alternation; the standard reconstruction assumes an *e* here, which is also generalized to the first stem of Classes I and II (*e* became *i* before the *i* and *u* of these classes as well as before the nasal of Class III). Thus, all three classes can be reconstructed with the same pattern (*e-a*) for the first two stems.

There remains the third stem, for which, as we have seen, we assume a 'zero vowel' for Classes I and II. If the pattern is the same for all three classes, Class III should have no vowel at all here, though in fact we find *u*. This *u* thus alternates with the *zero* of Classes I and II, and we can reconstruct a single source for both, which, following the first two classes, is taken to be *zero*. The nasal or liquid consonant of the stem of this class is assumed to have been 'syllabic' (i.e., it had the role of a vowel, as with the *n* or *l* of such English words as *bitten* (bitn) or *bottle* (botl)). It is presumed that these syllabic consonants later developed *u* before them. The result of these procedures is an entirely regular system, with the pattern *e–a–zero*, the differences among these three classes being in the sound which followed the vowel: *i* in Class I, *u* in Class II, and a nasal or liquid consonant in Class III. Such a regularized system can then be regarded as existing at an earlier stage of the language.

It is legitimate to object, of course, that, carried to its logical conclusion, this procedure results in the elimination of all anomalies and irregularities, and thus assumes that earlier languages had no such irregularities – an unlikely state of affairs. However, it should be borne in mind that all reconstruction, by whatever method, produces an idealization rather than an attested reality.

Universal and Typological Reconstruction

This method attempts to work backward by invoking known or assumed general attributes of language or processes of linguistic change. This is the most powerful, but also the most speculative form of internal reconstruction, since the evidence we have of such general processes of change is often of a theoretical kind.

The criteria for reconstruction here may be either universal or typological. In the former case, changes are assumed to have occurred which reflect universals, i.e., characteristics of all languages, though these may be diachronic (universal processes of change) or synchronic (universal characteristics of language states which constrain the processes of change). If we therefore encounter a particular feature in the language under investigation which is known to be the result of a certain universal process, then we may assume this process to have occurred and reinstate the form from which the feature may have derived.

Universal processes or constraints have been recognized for all components of linguistic structure: phonology, morphology, syntax, and the vocabulary. One such process, which is currently receiving considerable attention, is grammaticalization (*see* Grammaticalization), the 'downgrading' of lexical words to grammatical words and affixes (Hopper and Traugott, 1993); a similar and related process applies in the lexicon, by means of which words are progressively 'bleached' of semantic content. Recognition of such universals allows us to determine the direction of language change, and thus to reconstruct earlier stages in conformity with this direction. Thus, if we assume that all grammatical affixes are derived from original lexical words, then a reconstruction which posits grammatical morphemes as earlier stages of lexical morphemes rather than the reverse would be ruled out.

Reconstruction based on typological criteria relies on the observation that languages fall into a number of more or less distinct types, characterized by co-occurring or harmonizing features (*see* Linguistic Typology). A standard typological grouping, for example, divides languages into VO and OV types, according to whether the object (O) follows or precedes the verb (V). A number of other features of sentence structure harmonize with this: in VO languages (e.g., French) the adjective typically follows the noun, and prepositions are used;

in OV languages (e.g., Japanese) the adjective typically precedes the noun, and postpositions are used.

To apply the method, we identify the language as belonging to a particular type on the basis of some major feature, and, making the further assumption that languages are ideally typologically consistent, bring the remaining harmonizing features into line. If, for example, we find a language (such as English) which is VO but has the order adjective + noun, we will assume that at an earlier stage the language will have either been OV (which is assumed for English) or will have had the reverse order of noun and adjective. Various different typological parameters have been put forward, but their use in reconstruction generally follows the above procedure. Again there are potential weaknesses in the assumptions underlying the method, since most languages are typologically inconsistent to some degree, and it is by no means proven that typological consistency represents an ideal or original state for languages.

Conclusion

The methods of internal reconstruction are extremely powerful, but they rest on a range of assumptions about both the nature of languages and the nature and direction of language change. The accuracy and reliability of the results inevitably depend on the adequacy of these assumptions. Not surprisingly, the results of the method have often been challenged as the assumptions themselves have been called into question.

Internal Validity

Charles S Reichardt, University of Denver, Denver, CO, USA

This article is a revision of the previous edition article by M.M. Mark and C.S. Reichardt, volume 11, pp. 7749–7752, © 2001, Elsevier Ltd.

Abstract

The effect of a treatment is assessed by comparing what happened when the treatment was present to what happened when the treatment was not present. Anything else in such a comparison that varies along with the treatment is called a treatment confound and can bias the estimate of the treatment effect. Threats to internal validity are treatment confounds. Conclusions about treatment effects are said to be internally valid if they are unbiased by threats to internal validity.

Campbell (1957) introduced the notion of internal validity by contrasting it to external validity, and both types of validity were later detailed further in Campbell and Stanley (1963, 1966). In these early works, internal validity was said to address the question of whether a treatment had an effect in a given study, while external validity was said to address the question of whether the treatment effect in a given study could be generalized to treatments, outcomes, recipients, and settings beyond those in the given study. These definitions were widely accepted as gospel across the social sciences until Cook and Campbell (1976, 1979), not being satisfied with the diptych of types of validity, introduced two new types, statistical conclusion validity and construct validity. Correspondingly, Cook and Campbell also adjusted the definitions of internal and external validity to fit the more crowded landscape. Believing the concept was often misunderstood and therefore misused, Campbell (1986) subsequently suggested that internal validity be relabeled 'local molar validity' to emphasize that internal validity concerns only the results of a specific (local) study and that, in assessing its effects, the treatment was to be taken as a single undifferentiated (molar) manipulation. However, luckily, the awkward label of 'local molar' validity never caught on.

The latest revision of the Campbellian typology is by Shadish et al. (2002), who have maintained the distinction among the four types of validity but have once again somewhat modified the definitions. According to this latest version, internal validity concerns the presence or absence of a causal relationship between the treatments as manipulated and the outcomes as measured in a specific study; construct validity concerns which higher order constructs are represented by the treatments, recipients, settings, and outcomes in the given study; and external validity concerns whether the causal relationship between the treatments as manipulated and outcomes as measured holds across variations in treatments, outcomes, recipients, and settings.

Each type of validity can suffer from unique 'threats' to validity. Threats to internal validity are treatment confounds. The next sections define treatments confounds and the types of treatment confounds that threaten internal validity and explain how to either avoid or remove threats so as to achieve internal validity.

Threats to Internal Validity

The effect of a treatment (as compared either to no treatment or to an alternative treatment) is the difference between what would have happened at time 2 if the treatment had been implemented at time 1 and what would have happened at time 2 if either no treatment or an alternative treatment had been implemented at time 1, but everything else at time 1 had been the same. Such a comparison is called the 'ideal' comparison. As just noted, the effect of a treatment can be defined in reference to a comparison either between a treatment and no treatment or between a treatment and an alternative treatment. For ease of expression, but without loss of generality, the author sometimes refers to comparisons between a treatment and no treatment and sometimes to comparisons between a treatment and an alternative treatment. The same results hold in either case.

The ideal comparison, which is a comparison between what happens after a treatment is implemented and what happens after that treatment is not implemented but everything else is the same, is impossible to obtain in practice. In any comparison that can be obtained in practice, something else must vary along with the treatment. Whatever else varies along with the treatment is called a treatment confound. Treatment confounds can introduce biases in the estimates of treatment effects. Threats to internal validity are certain types of treatment confounds.

To make the definition of a treatment confound more concrete, consider two types of comparisons often used in practice to assess treatment effects. The first type of comparison draws a contrast between outcomes obtained at different points in time. The ideal comparison requires that a treatment both be given and not be given to the same people (who will be called recipients) at the same point in time. Although such a comparison is impossible to obtain in practice, it is possible to give a treatment and not give a treatment to the same recipients at different points in time. In particular, it is possible to compare what happens before a treatment is implemented to what happens after the treatment is implemented, which is called a 'before–after' comparison. In such a comparison, differences in performances between the before and after assessments are attributed to the effect of the treatment. Anything, in addition to the treatment, that occurs between the time of the 'before' assessment and the time of the 'after' points is confounded with the treatment. Like the treatment, a confound can cause a difference between the before and after assessments. Therefore, a confound could either counteract or supplement the effect of the treatment, so the effect of the treatment is either over- or underestimated by the before–after comparison.

The second type of comparison draws a contrast between different recipients. In such a comparison, a treatment and an

alternative treatment are implemented at the same point in time, but with different recipients. That is, one set of recipients receives the treatment, while, concurrently, a different set of recipients receives an alternative treatment. Subsequent differences in performance between the two treatment groups are attributed to the effect of the treatment. Such a comparison is called a between-group comparison. Anything, in addition to the treatment, that varies across the two sets of recipients is confounded with the treatment. Like the treatment, a confound can cause a difference between the outcomes of the treatment groups. Therefore, a confound could either counteract or supplement an effect of the treatment, so the effect of the treatment is either over- or underestimated by the difference in outcomes between the treatment groups.

A variety of threats to internal validity can arise due to confounds in each of the two types of comparisons just described above. The most prominent threats to internal validity are described below.

Maturation

Due to natural maturational processes, people can change over time in any number of ways. People can become more or less knowledgeable, more or less attentive, more or less tired, more or less hungry, and so on. Campbell (1957), who first introduced the notion of internal validity, called such changes 'maturation.' If the effect of a treatment is assessed in a before–after comparison (i.e., by comparing how recipients perform before a treatment is introduced to how they perform after the treatment is introduced), the treatment is confounded with whatever maturational changes occur between the time of the before and after assessments. Maturational changes can cause a change in the after assessment compared to the before assessment, and hence maturational changes can cause the treatment to look either more or less effective than it really is. Hence maturational changes are a threat to internal validity.

History

In a before–after comparison (where the performance before a treatment is introduced is compared to performance after a treatment is introduced), the treatment is an external event imposed on the recipients. Other external events, besides the treatment, can occur between the time of the before and after assessments and impinge on the recipients. Such external events are threats to internal validity because they can cause a change in the after assessment compared to the before assessment and hence cause the treatment to look either more or less effective than it really is. The effects of external events besides the treatment are called 'history' effects. As such, history is a confound and a threat to internal validity.

Instrumentation

In a before–after comparison, the measuring instrument used to assess performance before the treatment is introduced might differ in some way from the measuring instrument that is used to assess performance after the treatment is introduced. In the extreme, two separate measuring instruments might be used for the before and after assessments. The before and after instruments might objectively be the same but might be implemented in slightly different ways. Any change in the measuring instruments or in how the measuring instruments are implemented is called a change in 'instrumentation.' A change in instrumentation is a treatment confound and could bias the estimate of the treatment effect. Hence a change in instrumentation is a threat to internal validity.

For example, consider a 10-week long intervention intended to improve children's social skills where the pretest and posttest assessments are based on parental reports of their children's behavior. After attending the program for several weeks with their children, the parents might alter their perceptions of their children's behavior. Because of the program, the parents might come to recognize, say, problems in their children's behavior that they did not recognize before. As a result, the parents might rate behavior on the 'after' assessment more negatively than they would have rated the same behavior on the before assessment. Such a change would make the program look less effective than it really is. Because the parents are the instrument by which behavior is rated and because the way in which parents rate behavior changes, the bias in the estimate of the treatment effect is due to a change in instrumentation.

Testing

In a before–after comparison, the mere act of collecting a 'before' assessment can have an effect on the 'after' assessment. Such an effect is called a 'testing' effect. A testing effect can be confounded with the treatment and thereby be a threat to internal validity. For example, in an intervention designed to improve children's social skills, a pretest assessment that asks parents to rate their children's social skills might itself have an effect on the children's social skills, quite apart from the effects of the intervention. That is, simply by rating their children on social skills during the pretest assessment, parents might be led to recognize deficiencies in their children's social skills, and this might motivate the parents to improve their children's social skills even without the intervention program.

Testing effects are often confused with instrumentation effects. A testing effect is an effect of the assessment process on subsequent outcomes, while an instrumentation effect is an effect of a change in the assessment process. When testing has an effect, a real change has occurred in the behavior being assessed, due to the process of testing or assessment. Instrumentation effects result only in a change in the recorded level of the assessed behavior but not in a real change in the level of assessed behavior.

Seasonality

The different seasons (winter, spring, summer, and fall) can induce different behaviors. The same holds for different days of the week and different times of the day. Effects due to differences in seasons, days of the week, times of day, or any other cyclical variations are collectively called 'seasonality' effects. If the before assessment, in a before–after comparison, is made during a different season, day of the week, or time of day than the after assessment, part of the difference between the two assessments could be due to seasonality effects and not just the

effects of the treatment. Hence seasonality effects can bias the estimate of treatment effects and be a threat to internal validity.

Attrition

Some recipients might fail to complete an assessment in a before–after comparison because they drop out of the treatment or for some other reason. If the before assessment in a before–after comparison is based on the scores of all the recipients, while the after assessment is based on the scores of only those recipients who complete the program or complete the after assessment, observed differences between the before and after assessments might be due not just to treatment effects but also to differences in the two different groups of recipients. If those who drop out would have performed relatively poorly on the after assessment, the resulting bias in the estimate of the treatment effect will make the treatment look more effective than it really is. Conversely, if those who drop out would have performed relatively well on the after assessment, the resulting bias in the estimate of the treatment effect will make the treatment look less effective than it really is. When recipients drop out of either the treatment or the measurement process, the loss is called 'attrition.' As just demonstrated, attrition can be a confound and a threat to internal validity.

Regression toward the Mean

Recipients in a before–after comparison are sometimes recruited into a study based on their performance on the before (or pretest) assessment. For example, students who score poorly on a pretest assessment of cognitive abilities might be recruited to receive a remedial education program. Conversely, students who score well on a pretest assessment might receive benefits and rewards, such as a scholarship. A posttest assessment could then be conducted to determine the effects either of the remedial program or of the benefits and rewards.

Selecting recipients to receive a treatment based on either high or low scores on a pretest can introduce a bias due to regression toward the mean. When recipients are selected to receive a treatment because they have relatively low scores on a pretest, regression toward the mean causes the recipients' posttest scores to be relatively higher. When recipients are selected to receive a treatment because they have relatively high scores on a pretest, regression toward the mean causes the recipients' posttest scores to be relatively lower.

Regression toward the mean occurs because some of the causes of either high or low scores on the pretest assessment are likely the result of temporary factors that tend not to be as extreme on the posttest. For example, temporary factors that can cause a pretest score to be either relatively high or low include such things as obtaining high or low scores on a pretest because of either particularly good or poor guesses on a test, feeling under the weather or feeling particularly energized at the time of the pretest, being distracted by extraneous influences or being particularly attentive because of a good breakfast or welcome news received the morning of the pretest, and so on. However, such factors are not as likely to be as high or as low on the posttest as they were on the pretest because these factors were not selected to be either high or low on the posttest as they were on the pretest. If the factors are not selected to be either high or low, they are more likely, everything else being the same, to be middling rather than either high or low. As a result, recipients selected for low scores on the pretest will tend to have higher scores on the posttest even if the treatment has no effect. Conversely, recipients selected for high scores on the pretest will tend to have lower scores on the posttest even if the treatment has no effect. As long as recipients are selected for either high or low scores on a pretest and as long as the correlation between pretest and posttest scores is not perfect, regression toward the mean will tend to make the average posttest score closer to the mean than the average pretest score, independently of any treatment effect. Hence regression toward the mean is a threat to internal validity.

Carryover Effects

Consider a comparison in which two alternative treatments are given, one after the other, to the same group of recipients. In that comparison, the performance of the recipients is assessed after each treatment is given, and the relative effects of the two treatments are assessed by contrasting these two performances. If the effects of the treatments are short lived so the effect of the first treatment has worn off before the second treatment is implemented, the effect of the first treatment will not influence the outcomes on the second assessment. However, if the effects of treatments are not short lived, the effect of the first treatment might still be present when the second treatment is implemented. As a result, a comparison of the outcomes of the two treatments can be biased by the continuing effects of the initial treatment. Such a bias is said to be due to carryover effects. Carryover effects are a threat to internal validity.

For example, consider comparing two methods of teaching children to ride a bicycle. If the first method is effective, the children will not have forgotten how to ride a bicycle by the time the second method is introduced. Therefore, even if the first method is effective and the second method is not, there will be no difference in performance following the two treatments. The success of the first method of instruction will have carried over to influence the assessment of the second method of instruction.

Selection Differences

As noted above, in a between-group comparison, one group of recipients receives a treatment, a different group of recipients receives an alternative treatment, and subsequent differences in outcomes between these two groups are attributed to differences in the effects of the treatments. No two groups of recipients are identical. One group will be smarter and one group will not be as smart, on average, even if the difference is only very slight. Similarly, one group will be taller and one group will be shorter, on average. One group will be more attentive and one group will be less attentive, on average, and so on. Whatever differences exist between the two groups of recipients before the different treatments are introduced in a between-group comparison are called selection (or baseline) differences. Selection differences are a threat to internal validity because a difference in outcomes between the treatment groups could be due either to the effects of the treatment or to the effects of selection differences.

Interactions with Selection

In a between-group comparison, the effects of selection differences can interact with the effects of other threats to internal validity. For example, history is a threat to internal validity in a before–after comparison that arises when an external event besides the treatment occurs in between the time of the before and after assessments. A bias can be introduced in a between-group comparison if different external events, besides the different treatments, are introduced in the two different treatment groups. Such a bias is said to be due to local history effects or to a selection by history interaction.

Similarly, attrition can be a threat to internal validity in a before–after comparison when some recipients drop out of the study. A bias can be introduced in a between-group comparison if different types of recipients drop out of the different treatment groups. Such a bias is said to be due to differential attrition or to a selection by attrition interaction.

Other threats to internal validity in a before–after comparison–including threats due to maturation, testing, instrumentation, seasonality, and regression toward the mean–can also introduce biases in a between-group comparison when the effects of the threats operate differentially across the groups. In such cases, the threats are said to interact with selection.

Crossover Effects

In a between-group comparison, recipients who are supposed to receive one of the two treatments might manage in some way to receive the other treatment instead. Such unauthorized reassignment of treatments is called treatment 'crossover' and is a threat to internal validity. For example, if an innovative treatment is more effective than a standard treatment, if recipients tend to cross over from the standard treatment to the innovative treatment, and if the recipients who cross over tend to be those who would perform poorly no matter which treatment they receive, crossovers will tend to make the innovative treatment appear less effective than it really is, and vice versa.

Coping with Threats to Internal Validity

To estimate treatment effects without bias, researchers must either avoid the effects of threats to internal validity so they are never present or remove them when they are present. A variety of design features and statistical procedures have been developed either to avoid or remove the effects of threats to internal validity (Reichardt, 2000; 2009). A few of the most common design features and statistical procedures are described below.

Interrupted Time-Series Designs

As noted above, a simple before–after design is susceptible to a number of threats to internal validity. One way to cope with those threats to validity is to add design features to embellish the comparison. One slightly more elaborate design includes multiple observations spread out at regular intervals both before and after the treatment is implemented. In such a design, the effect of the treatment is no longer estimated as the difference between a single pretest and a single posttest observation. Instead, the effect of the treatment is estimated by assessing the trend across time that exists in the pretest observations, projecting that trend forward in time, and comparing the projected trend to the actual trend in the posttest observations. Discrepancies are attributed to the effect of the treatment. Such a design is called an interrupted time-series (ITS) design.

Maturation is no longer a threat to validity in an ITS design because the effect of maturation, if modeled correctly by the trend in the pretest observations, is taken into account and removed. Similarly, the effects of testing are typically rendered implausible because testing effects are unlikely to continue across the multiple pretest observations that are collected before the treatment is introduced. Regression to the mean is also rendered implausible to the extent selection into the treatment is based on one of the earliest pretest observations.

An ITS design can be elaborated further by adding a comparison time series of observations. The recipients who receive the treatment provide the experimental time series of observations. Recipients who receive an alternative treatment (or no treatment) provide a comparison time series of observations. A treatment effect is estimated in each time series. The differential effect of the treatments is estimated as the difference between the estimates from the two time series. The effects of history, instrumentation, and seasonality are controlled in such an estimate to the extent these effects are the same in the two time series of observations. Further design embellishments, such as adding nonequivalent measures and treatment variations, are also possible and correspondingly can help rule out additional threats to validity (Shadish et al., 2002).

Random Assignment to Treatment Conditions

The purpose of randomly assigning recipients to treatment conditions in a between-group comparison is to cope with the biasing effects of selection differences. Contrary to what is sometimes stated, random assignment to treatments does not remove all selection differences. Rather than completely removing selection differences, random assignment makes selection differences random. The effects of these random selection differences can then be assessed using the classic statistical procedures of hypothesis tests and confidence intervals. To the extent the differences between the groups on the outcome measure are greater than chance effects due to the random selection differences, the treatment is estimated to have an effect above and beyond the effects of selection.

Another advantage of random assignment is that the effects of random selection differences can be made as small as desired simply by increasing the number of recipients (i.e., the sample sizes) in the treatment groups. As a result, random assignment can be a powerful means of addressing the threat to validity of selection differences. However, random assignment does not control all threats to internal validity. Differential attrition, local history, and crossover effects can still plague randomized experiments if researchers are not vigilant in avoiding these sources of bias.

Regression-Discontinuity Designs

Instead of assigning recipients to treatment conditions at random, recipients could be assigned using a quantitative

measure of need or merit. Those recipients whose score on the quantitative measure falls below a specified cutoff value would be assigned to one treatment group, while those recipients whose score on the quantitative measure falls above the cutoff value would be assigned to the other treatment group. The effect of the treatment is assessed by regressing the outcome scores onto the quantitative measure in each treatment group to produce a regression line in each group. A break in these regression lines at the cutoff value is attributed to the effect of the treatment. Because the analysis of the data looks for a discontinuity between the two regression lines, the design is called a regression-discontinuity (RD) design.

The RD design takes account of the effects of selection differences by modeling their effects much as an ITS design takes account of the effects of maturation (Marcantonio and Cook, 1994). An RD design can sometimes be implemented when a randomized experiment is not feasible because of administrative or ethical constraints. The disadvantage of the RD design, compared to a randomized experiment, is that the estimate of the treatment effect in the RD design requires additional assumptions and is less precise.

Matching and Propensity Scores

When recipients are assigned to two treatment conditions neither at random nor according to the specifications of an RD design, a between-group comparison becomes a nonequivalent comparison group (NECG) design. Estimates of treatment effects from an NECG design are generally less credible than estimates from either randomized experiments or RD designs because researchers cannot be as certain that the effects of selection differences have been properly modeled and removed. One of the most credible methods for taking account of the effects of selection differences in an NECG design involves matching the recipients in the different treatment groups using propensity scores (Rosenbaum and Rubin, 1983). As with ITS designs, a wide range of design and statistical embellishments can be added to between-group comparisons to take account of additional threats to validity, such as due to differential attrition, local history, and crossover effects.

Conclusion

Although firmly entrenched in textbooks on research methods across the social sciences, the Campbellian conceptualization of validity, across its evolution, has oft been challenged and criticized (Cronbach, 1982; Kruglanski and Kroy, 1975; Reichardt, 2006, 2011). One set of disputes about the Campbellian typology concerns priorities among the four types of validity. An inherent premise of the Campbellian perspective, which has been consistent over time, is that internal validity is the most important of the four types for causal inference. Without internal validity, satisfying the other three types of validity hardly advances causal inference at all. In contrast, Cronbach has argued that external validity is paramount. However, regardless of relative priorities, no serious scholar of research design doubts that internal validity is a central and fundamental building block of sound causal inference.

Abstract

International advertising is a communication process that takes place in multiple cultures and contexts that differ in terms of values, economic development, media infrastructure, communication styles, and consumption patterns. This context shapes consumption behavior and influences how individuals respond to advertisements. International advertising is also a business activity involving advertisers who are expanding the market for their goods and services. These activities are facilitated by the advertising agencies that conduct research, create advertisements, and select media for the ads. The sum total of these activities constitutes a worldwide industry that is growing in importance and influence. International advertising is a major force that both reflects social values and helps reinforce or shape certain values worldwide.

Definition of International Advertising

International advertising entails dissemination of commercial messages to target audiences in more than one country. Its goal is to facilitate the sale of goods and services, although it may also involve advertising designed to gain acceptance of ideas and practices. One of the main challenges international advertisers face is dealing with the complexity of the diverse environments in which they advertise as well as the heterogeneity of individuals across and within countries. Advertising typically is deeply embedded in a particular culture and shaped by the context in which it takes place. Interpretation of symbols used in the advertisement, response to humorous or emotional appeals, and levels of literacy and languages spoken all influence how effective the ads are. The intended audiences differ from country to country in terms of how they perceive and respond to the advertisements. Also, consumers differ in terms of their basic needs, product preferences, and the ability to purchase products and services. The availability of media to convey messages to target audiences differs across countries. The organization of the advertising function also varies. In some cases, multinational firms centralize advertising decisions and budgets and use the same or a limited number of agencies worldwide. In other cases, budgets are decentralized and placed in the hands of local subsidiaries, resulting in greater use of local advertising agencies. These different organizational structures can also influence the types of advertisements that are created and how closely they are linked to the local culture. In situations where advertising decisions are highly centralized, the ads are often the same with minor modifications or incorporate a similar theme. When advertising decisions are decentralized, the advertisements are more likely to be highly diverse reflecting local idiosyncrasies.

At its core, international advertising is a communication process that takes place in multiple cultures and contexts that differ in terms of values, economic development, media infrastructure, communication styles, and consumption patterns. These contexts shape consumption behavior and influence how individuals respond to advertisements. International advertising is also a business activity involving advertisers who are interested in expanding the market for their goods and services. These activities are facilitated by the advertising agencies that conduct research, create advertisements, and select media to place the ads. The sum total of these activities constitutes a worldwide industry that is growing in importance and influence. International advertising is also a major force that both reflects social values and helps reinforce or shape certain values worldwide. The remainder of this article examines international advertising from these different perspectives to provide a better understanding of its role and impact on society.

The Context of International Advertising

Part of the complexity of international advertising derives from the diverse contexts in which it occurs. Advertising has long been practiced in highly industrialized countries such as the United States, countries in Western Europe, and parts of Asia. It is also a major factor influencing consumption choices being carried out in large countries whose economies are not as highly developed, but growing rapidly, such as China, Russia, and India. Furthermore, it is evident in the Middle East and Africa, but with significant variation by country. Countries differ in terms of the level of economic development, level of education, cultural values, climate, and religious traditions, among other factors. Variations in human behavior and attitudes are a set of collective and individual adaptations to contextual factors and more specifically the ecological and sociopolitical systems (Mishra et al., 1996). Individuals interact with and adapt to their physical environment in order to satisfy basic needs such as food, shelter, friendship, and achievement. Six principal contextual dimensions have been identified that influence choices and psychological values across countries: ecology, economy, education, mass media, population, and religion (Georgas et al., 2004). Mass media is the main conduit for advertising and is in turn shaped by contextual factors. Similarly, these factors impact consumer values, attitudes, and behavior patterns since these are deeply embedded in and to a large extent formed by overall social values. Three distinct categories of contextual variables relevant to behavior as consumers can be identified: the ecological context, the level of social affluence, and the religious context.

The ecological context, measured in terms of factors, such as average levels of precipitation or temperature or climatic zone, has been found to influence both values and consumption

patterns. For example, ecological factors have been found to impact value orientations and psychological variables such as involvement, power distance, and individualism (Georgas et al., 2004). Climate has been found to have an important influence on the consumption of pharmacological products such as alcohol, cocoa, coffee, tea, and tobacco (Parker, 1997).

In addition to the role of ecological factors in shaping culture, sociopolitical and economic factors are formative elements. Wealth, education, employment, governmental, and social institutions both foster and filter adaptation to the physical environment. The affluence of society is a powerful factor impacting culture and mediating its role on consumer behavior. Levels of GDP per capita have, for example, been found to be correlated with national value orientations and in particular, with Hofstede's measures of individualism and collectivism (Hofstede, 2001). Highly developed countries are more likely to have high levels of individualism and to value individualistic goals such as personal achievement and ambition. These are often important motivational factors driving the engine of economic growth and entrepreneurship. Furthermore, in poor countries, people depend on support from in-groups such as families or local communities, but as wealth increases, individuals gain access to resources which enable them to make their own personal choices and spend according to their own individual interests. Advertisers need to account for these differences in underlying value orientations in creating advertisements.

The level of education in a country measured, for example, in terms of factors such as levels of illiteracy, educational attainment, expenditure on R&D, also impacts culturally embedded consumption behavior. For example, Katz-Gerro (1999) found that individuals with high levels of education are more likely to engage in certain leisure activities. They are more likely to be ecologically concerned and to purchase in environmentally friendly stores such as The Body Shop or Whole Foods Markets and to be more concerned with fitness and health, to exercise regularly, and belong to gyms and health spas (Lee and Holden, 1999). Also they are more likely to be aware and open to ideas and information from other cultures and be willing to try unfamiliar products from other countries, even if these are relatively expensive exotic foods, such as frog's legs or truffles (Nijssen and Douglas, 2008). These tendencies and beliefs influence whether advertising campaigns for environmentally friendly products or novel products are likely to be successful in a particular locale.

Social, economic, and political institutions also play an important role in forming and perpetuating cultural patterns and behavior. In some societies, there are social hierarchies such as the social class structure typical of certain Western European countries or the caste system in India. Membership in a given social class, often defined by a combination of occupation, wealth, and birth, implies a certain social status. Each social class is bound by a system of social norms and obligations, and social interaction occurs predominantly within members of the same group, resulting in pressures for social conformity and similar consumption patterns. When creating advertising appeals, these differences need to be taken into account to maximize the effectiveness of the message.

Since wealth and possessions are a key factor defining membership in a given social class, the distribution of wealth is often closely linked to the degree of social stratification and hence variation in consumption patterns within society. Many Latin American countries, with highly skewed income distribution, are also marked by high variation in consumption patterns and price sensitivity. Stratified societies also vary in terms of the extent to which individuals are tightly enmeshed in the social structure or rather are free to develop their own lifestyles and patterns of social interaction. Conversely, in egalitarian societies, such as the Scandinavian countries, Japan, or Iceland, there is substantial social homogeneity and minimal variation in consumption patterns and behavior. In the latter case, one set of advertising appeals is likely to be sufficient, whereas in a very hierarchical society, a more segmented approach would need to be taken.

Religion is another factor with a strong influence on cultural values and consumption patterns. Some religions, e.g., Judaism, Islam, Hinduism, have very clearly prescribed rules for consumption behavior, particularly with regard to food and alcohol, which in some cases also extends to dress, particularly for women. Strong religious beliefs also are typically associated with conservative traditional values (Spika et al., 1985) with regard to social conformity and social issues such as feminism, divorce, and sexuality. These, in turn, may have either a direct or an indirect effect on the behavior of consumers and, in particular, responses to certain types of advertising appeals or product-positioning strategies.

Contextual factors play a key role in the formation and perpetuation of cultural values and behavior, as well as directly impacting attitudes and behavior as consumers. Interactions within the family unit and with friends, teachers, or colleagues at work, or members of other social and religious organizations to which an individual belongs mediate the impact of macro-environmental forces. In some cases, these interactions may reinforce the impact of contextual variables on individuals' behavior. In other cases, they may mediate their influence on values, attitudes, and behavior and act as barriers to change at a societal or an individual level. Contextual factors are thus important elements influencing consumer attitudes and behavior. Even where their influence is subtle and indirect, they need to be taken into account when developing international advertising strategy.

Research for International Advertising

Given the complexity of operating in multiple countries and contexts, a critical component of successful international advertising is research designed to develop a clearer understanding of consumer preferences, values, attitudes, and current behaviors. International advertising research is designed to facilitate the creation, refinement, and evaluation of advertising. It involves respondents and researchers from different countries and cultures and is more complex to undertake and more difficult to interpret than research carried out in a single country (see Craig and Douglas (2005) for a comprehensive treatment of international marketing research). Based on the understanding gained in the research, the advertiser is able to formulate strategies that can be turned into concepts and rough advertisements which can be tested and refined. The research also is able to help the advertiser determine whether a common

advertising campaign can be run in multiple countries or whether each country requires a separate strategy. Once the ads are run, the emphasis shifts to evaluating whether the campaign achieved the desired results.

The most critical factor in making meaningful inferences about advertisements in different countries is to be certain that the ads, themes, or potential strategy that consumers are reacting to are equivalent. To do this, the data must be comparable and equivalent from one country to another. The three main types of equivalence are *construct* equivalence, ensuring that the constructs are equivalent in all contexts and cultural settings; *measure* equivalence, ensuring that operational measures are equivalent in all research settings; and *method* equivalence, ensuring that data collection procedures are comparable and equally reliable in all contexts studied.

Construct equivalence has three distinct aspects. First, the advertiser must assess *functional* equivalence, whether a given concept or behavior serves the same function from country to country. Concepts, objects, or behaviors studied may not necessarily be functionally equivalent, that is, they may not have the same role or function in all countries studied. The second type of equivalence is *conceptual* equivalence and requires the advertiser to determine whether the same concepts or behaviors occur in different countries and whether the way in which they are expressed is similar. Functional equivalence is concerned with the role of objects and behavior in society at a macrocultural level, while conceptual equivalence is concerned with the interpretation that individuals place on objects, stimuli, or behavior, and whether these exist or are expressed in similar ways in different countries and cultures. Finally, the advertiser must assess *category* equivalence to determine whether the concept belongs to a specific class of objects or activities. The category in which objects or other stimuli are placed can vary from country to country. Variation in categories between countries creates different competitive sets and can influence advertising strategy.

Once the advertiser is confident that the constructs are equivalent, or has determined where there is divergence, the next step is to examine the equivalence of the measures used. Construct and measure equivalence are interrelated as the measure is an operational definition of the construct. Measure equivalence has three main dimensions: the calibration system used in measurement; the translation of the research instrument; and the metric equivalence of the instrument (Mullen, 1995). In developing a research instrument, equivalence has to be established with regard to the calibration system used in measurement. This includes not only equivalence with regard to monetary units and measures of weight, distance, and volume but also other perceptual cues, such as color, shape, or form, which are used to interpret visual stimuli. Advertising stimuli are complex and contain a large amount of information. They contain subtle perceptual cues such as color, pictorial form, or shape. Studies in cognitive and cross-cultural psychology suggest that a substantial degree of commonality exists with regard to the manifestations of these in different countries and cultures (Russell et al., 1997). However, ability to interpret, differentiate among, and develop gradations in these appears to differ. Often this is linked to schooling, language, and the physical environment. Translation equivalence is a central issue in the establishment of construct equivalence, since this is the stage in the research design at which the construct is defined in operational terms. The translation procedure may help pinpoint problems with regard to whether a concept can be measured by using the same or similar questions in each cultural context, and whether a question has the same meaning in different research contexts (Douglas and Craig, 2007). If different questions are used, then issues arise with regard to the minimal level of equivalence necessary for two questions to be considered the same, and what criteria for equivalence can be established.

In establishing metric equivalence, there are two main issues related to the equivalence of the scale or scoring procedure used to establish the measure, and the equivalence of response to a given measure in different countries (Mullen, 1995). The greater the emphasis placed on quantitative measurement in data interpretation, the more important the establishment of metric equivalence becomes. A second aspect of metric equivalence concerns the interpretation of a score obtained on a measure, or scalar equivalence. The question arises as to whether a score obtained in one research context has the same meaning as in another context.

Development of international advertising strategy must be guided by research that is valid and reliable and that provides adequate direction for the formulation of advertising strategy. While the issues of comparability and equivalence are the most critical, there are also other key issues. To begin with, a representative sample must be drawn of the target market or from a broader group of respondents to help define the target market. Research instruments suitable for use in all the countries or cultures have to be developed, a sampling plan developed, and appropriate administration procedures selected. Once the data have been collected, they have to be analyzed and the findings need to be presented in a form that can help facilitate development and evaluation of international advertising campaigns.

International Advertising as a Communication Process

In international markets, the process of communicating to a target audience is more complex because communication takes place across multiple cultures and contexts, which differ in terms of language, literacy, religion, and other cultural factors. Creating added complexity is the fact that media differ in their availability and in their effectiveness in conveying different appeals. A message may, therefore, not be effectively communicated to the intended audience for a variety of reasons. Structural reasons relate to the basic media infrastructure including the availability of certain media and the number of households that can be reached by a particular medium. Any advertising campaign that relies on the Internet will be severely limited in countries with low rates of Internet penetration. For example, Internet penetration rates in North America are almost 85%, making it an effective medium to deliver advertising messages to prospective customers. Furthermore, the 15% of households without an Internet connection may be of less interest to advertisers, as they may be older or have lower incomes. A very different picture is evident in Asia, where less than 32% of the households have

Internet access and in Africa less than 21% of the households have Internet access. The availability and penetration of more traditional media also varies. According to statistics compiled by Nationmaster.com, there were 803 television sets per 1000 inhabitants in the United States, 521 per 1000 in the United Kingdom, 65 per 1000 in India, and only 3.3 per 1000 inhabitants in Tanzania. Advertising campaigns relying on television as the main medium will be unable to effectively reach target audiences in countries with low household penetration. Alternative media may be found but if the advertisement requires sight and sound to communicate the message, its effectiveness will be diminished.

A particular medium may be available in a country and has sufficient household penetration to warrant its use, however, specific media vehicles to reach a target audience may be lacking. For example, *Cosmopolitan* magazine may be viewed as an appropriate media vehicle to reach women aged 18–34 and is also desirable due to editorial content that is compatible with the advertised product. However, if it is not available in that country, a substitute will have to be found. The substitute magazine may not reach the target as effectively, or it may lack the compatible editorial content. In addition to structural problems, there are more subtle issues related to people's inability to understand the advertisement, due to low levels of literacy. Advertising messages may be misinterpreted if different meanings are assigned to the words or symbols used. In instances where the message is adequately communicated, consumers may not respond to the message due to a lack of income to purchase the advertised product.

The communication process in international markets involves a number of steps. First, the advertiser in conjunction with the advertising agency determines the appropriate message for the target audience. Next, the message is encoded so that it will be clearly understood in different cultural contexts. There may be one central message that is unchanged, except for translation into multiple languages. Alternatively, the cultural contexts may be sufficiently varied that the message will have to be altered for each context. The message is then sent through media channels to the audience who decodes and reacts to the message. At each stage in the process, cultural barriers may hamper effective transmission of the message and result in miscommunication.

In encoding a verbal message, care needs to be taken in translation. Numerous examples exist of translation problems with colloquial phrases. For example, when the American Dairy Association entered Mexico with its 'Got Milk?' campaign, the Spanish translation read 'Are You Lactating?' conveying an entirely different meaning. Low levels of literacy may result in the need to incorporate visual symbols as the primary means of communicating. Here again, pitfalls can arise due to differences in color association or perception. In many tropical countries, green is associated with danger and has negative connotations. Red, on the other hand, is associated with weddings and happiness in China. Appeals to humor or sex need to be treated with considerable care as their expression and effectiveness varies from one culture to another. The dry British sense of humor does not always translate effectively even to other English-speaking countries. In many Muslim countries, extreme care must be taken on how females are depicted in advertisements as well as how male/female relations are portrayed.

In addition to encoding the message so that it attracts the attention of the target audience and is interpreted correctly, advertisers need to select media channels that reach the intended target audience. As indicated earlier, use of TV advertising may only reach a relatively select audience in certain countries. Equally, print media will not be effective where there are low levels of literacy. Certain media may also be more effective in certain cultures. For example, radio advertising has substantial appeal in South America where popular music is a key aspect of the local culture.

In addition to the influence of contextual factors covered in the 'The Context of International Advertising' section, the cultural context also impacts the effectiveness of communication. In what has been termed 'high-context' cultures, such as Japan and China, the context in which information is embedded is as important as what is said (Hall, 1976). In 'low-context' cultures, which include most Western societies, the information is contained in the verbal messages. In these cultures, audiences tend to demand explicit informational content (De Mooij, 2009). Conversely, people in high-context cultures are often more responsive to image or mood appeals, and rely on personal networks for informational content.

International Advertising as a Business Practice

When a firm develops an international advertising strategy, one important issue is whether to develop a global advertising campaign suitable for all countries, a regional advertising campaign for a specific part of the world, or to tailor communications to differences in local markets (Mueller, 2011). If the purpose of advertising is to develop a strong corporate or global image for the firm, a uniform global campaign is more likely to be used. When, on the other hand, the objective is to launch a new product or brand, or to more clearly differentiate the product or brand from other competing brands or products, local campaigns tailored to local markets are more typical.

A global campaign offers a number of advantages. In the first place, it can be an important means of building a strong and coherent global image for the firm and its products worldwide. Use of the same image in different countries builds familiarity and generates synergies across world markets. It allows utilization of good ideas and creative talent (both of which are scarce commodities) on a worldwide basis. In addition, use of a single campaign can result in substantial cost savings in copy development and production costs. Conversely, development of multiple local campaigns can lead not only to duplication of effort but also different messages in different countries. Given the increased reach of media across borders, ads run in one country may spill over into other markets. This can result in inconsistent brand images across countries and confusion in consumers' minds with regard to the benefits offered by the brand and the corporate image.

While use of uniform advertising appeals offers a number of advantages, differences in customer perceptions and response patterns across countries and cultures as well as media availability and government regulation are major barriers to use of a standardized campaign. Even though technological developments allow adaptation of advertising appeals to different languages (for example, TV can have audio channels in two

languages, Internet messages can be automatically translated), development of visual and verbal copy that works effectively in multiple countries poses major creative challenges.

Faced with this dilemma, firms may use a global umbrella campaign combined with local country- or product-specific advertising. The global umbrella campaign develops a uniform image for the company or brand worldwide, often relying on consistent visual images and the corporate logo. Product-specific or country-specific advertising builds on this image, modifying the appeal and providing information tailored to the local market. The objective of the umbrella campaign is to provide an integrating force, while local campaigns provide greater relevance to specific needs of local customers and markets.

The organizational structure of the firm often plays a key role in the choice of global versus locally adapted campaigns. If international operations are organized on a country-by-country or geographic basis and operate as local profit centers with local advertising budgets, pressures exist for use of local advertising campaigns. If, on the other hand, the company is organized by product divisions, with centralized advertising budgets at corporate or regional headquarters, use of regional or global advertising campaigns is more likely (see Douglas and Craig (2011) for more information on global strategy).

International Advertising as an Industry

The global advertising industry is characterized by a large number of small- and medium-sized advertising agencies that operate primarily in one country and by a small number of very large advertising agencies with operations in many countries. These agencies have developed extensive networks of offices throughout the world in order to coordinate the advertising process in all the countries where their clients do business. These networks often include both wholly owned subsidiaries and formal relationships with local advertising agencies to establish a presence in new markets, particularly in emerging markets.

In an effort to establish greater control over their advertising, many major advertisers are consolidating all their advertising with one agency. For some major advertisers such as IBM and Citibank, this represents annual advertising expenditures in excess of $500 million worldwide (Grein and Ducoffe, 1998). As a consequence, advertising agencies that do not have a global network are at a serious disadvantage when competing for new advertising accounts or attempting to retain existing ones that are expanding globally.

The majority of these large advertising agencies are headquartered in the United States although the ownership structure of the agency holding companies is more diverse. Of the seven largest advertising agency groups, two are headquartered in the United States, two in France, one in the United Kingdom, and two in Japan. The largest agency group, WPP, is a British agency holding company made up of four large US-based agencies as well as other firms that provide marketing communication services. WPP's revenues in 2013 were $18 billion (US dollars) with two-thirds of the revenue coming from outside the United States. WPP has 3000 offices in 110 countries and employs 179 000 people worldwide. The companies in the WPP group provide a wide range of services beyond advertising including marketing research, public relations, branding consulting, direct marketing, and digital marketing. With the exception of Dentsu and Hakuhodo, in Japan, most other agency networks generate the majority of their revenues outside their home country. Collectively, US-based advertising agencies and their subsidiaries are responsible for most of the advertising throughout the world. For example, of the approximately $60 billion in advertising placed by the top 25 agency networks in Europe during 1995, 89% of the total was placed by subsidiaries of US-based agencies. This general pattern holds in most parts of the world that do not have restrictions on foreign ownership. The major exception is Asia where the three major Japanese agencies account for 62% of the advertising placed by the top 25 agency networks. Current and comprehensive information on advertising can be obtained from *Advertising Age's* Web site, although there is a fee (www.adage.com).

Worldwide over $500 billion is spent on advertising annually. Approximately one-third of that amount is spent in the United States and the other two-thirds outside the United States. Information on advertising spending can be obtained from *Advertising Age's* Web site and from ZenithOptimedia's Web site (www.zenithoptimedia.com). The bulk of expenditures outside the United States takes place in Europe and Japan, although China, Brazil, Canada, and Australia are also important advertising markets.

The table below shows projected advertising spending in the top 10 global ad markets for 2016. The United States and Japan account for 59% of the total advertising spending in these markets and the four European markets account for an additional 20%. The concentration of spending in the United States in part explains the dominance of US-based advertising agencies. Not only do they work for US-based clients that continue to expand outside the United States, but they also accumulate knowledge, expertise, and experience in the practice of advertising that can be applied elsewhere.

Country	*Projected 2016 advertising expenditures (billions, US dollars)*	*Percent*
The United States	191.4	45
China	57.3	13
Japan	56.3	13
Germany	24.1	6
The United Kingdom	23.9	6
Brazil	20.2	5
Australia	14.3	3
Indonesia	14.2	3
South Korea	13.3	3
France	13.1	3
Total	421.3	100

Note: The expenditures reflect major media such as TV, the Internet, mobile, magazines, newspapers, radio, outdoor, and cinema. Total advertising spending for the entire world is projected to be $603 billion in 2016 and the top 10 countries account for 71% of the total.

Once the advertising message has been created, a media plan must be developed and specific media vehicles purchased to deliver the message to the target audience. This is either handled by the advertising agency or increasingly being done by specialized media buying organizations. Media differ from country to country in terms of their availability, effectiveness, and efficiency in delivering a message, and with relatively few exceptions, tend to be organized on a country-by-country basis. Notable exceptions include many Internet sites, Star TV, MTV, CNN in television, *Business Week International*, the *Asia Wall Street Journal*, the *International New York Times* in print, and selected industry and medical publication that are read worldwide. There is also a trend toward consolidation of media in order to achieve greater economies of scale and leverage content developed in one market to others. This consolidation facilitates purchase of media on a regional and global basis. In addition, the Internet is emerging as a truly global medium that does not conform to country boundaries. Web sites like Google and eBay have a global presence, although they do have local competitors. In 2014, Facebook had over 1.35 billion users and 82% were outside of the United States. Consistent with this, Facebook was available in over 70 languages (www.facebook.com). Most of the growth in advertising spending has been related to the Internet. Increased Internet penetration throughout the world is causing firms to either spend more on advertising or simply to shift expenditures from traditional media to the Internet.

International Advertising as a Social Force

From the advertiser's perspective, the primary objective of advertising is to sell products or services. In achieving this primary goal, there are often profound secondary consequences. Advertising exerts a formative influence throughout the world whose character is both pervasive and persuasive. Through the selective reinforcement of certain social roles, language, and values, it acts as an important force fashioning the cognitions and attitudes that underlie behavior not only in the market place but in all aspects of life. In an international setting, advertising has an important social influence in a number of ways. First, much international advertising is designed to promote and introduce new products that have been successful in one society into another. Often this results in radical changes in lifestyles and behavior patterns of a society, stimulating, for example, the adoption of fast food, casual attire, or specific beauty products. International advertising also encourages desire for products from other countries, as it creates expectations about 'the good life,' and establishes new models of consumption. Advertising is thus a potent force for change, while selectively reinforcing certain values, lifestyles, and role models.

Often the symbols, ideals, and mores that international advertising portray and promote are those of Western society and culture. Through global advertising, brands such as Levi's, Nike, Adidas, and McDonalds are known by and have become objects of desire for teens and young adults throughout the world. Consumers are exposed to advertisements for luxury goods such as Hermes, Rolex, Louis Vitton, and Gucci, whether or not they are available for sale in their country. Similarly, images and scenes depicted in much international advertising are either Western in origin or reflect Western consumption behavior and values. Even where adapted to local scenarios and role models, those shown often come from sectors of society, such as the upwardly mobile urban middle class, which embrace or are receptive to Western values and mores.

A criticism frequently leveled at international advertising is that it promulgates Western values and mores, notably from the United States, in other countries. This is viewed particularly negatively in societies with strong religious or moral values, which run counter to those of the West as, for example, Islamic societies in the Middle East. When Western advertising relies on sex to sell products or shows women in situations considered inappropriate or immoral, it is likely to be considered a subversive force undermining established cultural values. Equally, in some countries such as France, there is a strong negative reaction to the encroachment of US culture, values, and use of English in advertising. Promotion of tobacco products by US and UK companies in countries where there is no legislation regulating or banning cigarette advertising has also been criticized.

At the same time, international advertising acts as an integrating force across national boundaries. It disseminates messages using universal symbols and slogans, and establishes a common mode of communication among target audiences in different parts of the world. At the same time, multicultural values are reinforced by advertisers, who adopt images incorporating peoples of different nations and diverse cultural backgrounds. Coke Zero created a campaign that involved a search for dancers worldwide to star in their ads and Microsoft's television campaign for Windows-based phones that ran in 35 countries had a common theme, contained no dialog, and was tailored to various regions by using actors of difference ethnicities and local music. The impact of such campaigns is further reinforced by the growth of global media such as Star TV, CNN, MTV, or print media that target global audiences worldwide. Consequently, while international advertising can be viewed by its critics as a colonizing force propagating Western values and mores throughout the world, it is also an important force integrating societies and establishing common bonds, universal symbols, and models of communication among peoples in different parts of the globe.

International and Comparative Criminology

Amy Nivette, Nuffield College, Oxford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The terms 'international' and 'comparative' criminology are often used interchangeably to refer to any research concerning crime or criminal justice that either takes place outside the researcher's country of origin or involves more than one country. Each term refers to a wide body of rich comparative research that frequently intersects both theoretically and methodologically. This article gives a broad overview of comparative research, with a focus on (1) the methodological strengths and weaknesses, (2) the state of knowledge in macro- and microlevel comparative research, and (3) regional characteristics of crime.

Introduction

Crime is a multifaceted problem that faces societies of every country and every historical period (LaFree, 2006). As such, criminologists are faced with a growing body of potential explanations and solutions to the widespread, but varying, problem of crime. It is the task of comparative criminologists to explore which explanations are universal, which operate according to situational context, and which are culturally specific (Karstedt, 2001; Stamatel, 2009). Comparative researchers have already made many important contributions to the understanding of crime, violence, and criminal justice, in some cases confirming and in others rejecting common explanations.

The terms 'international' and 'comparative' criminology are often used interchangeably to refer to any research concerning crime or criminal justice that either takes place outside the researcher's country of origin or involves more than one country. Stamatel (2009) offers a more nuanced distinction between international and comparative criminology. International criminology is a general term that refers to crime or criminal justice trends in one or more countries. International criminology is not necessarily comparative since the focus of research may be on a single country; however, international comparisons are often implicit in single-country studies. Comparative criminological research is designed to investigate differences in crime and criminal justice organizations across borders. Often comparisons are made across international borders but may involve other units of analysis, such as cities, organizations, provinces, or regions. Falling under the banner of both international and comparative criminology is the more specific disciplinary term 'cross-national' criminology (Stamatel, 2009). Cross-national criminology refers to the study of crime across countries, typically with nations as the unit of analysis.

Overall, each term refers to a wide body of rich comparative research that frequently intersects both theoretically and methodologically. International comparative research covers everything from descriptive studies on the prevalence of theft in China, to multicountry school-based studies testing the universal relevance of self-control, to large-scale country-level studies testing theories of modernization. This article gives a broad overview of comparative research, with a focus on (1) the methodological strengths and weaknesses, (2) the state of knowledge in macro- and microlevel comparative research, and (3) regional characteristics of crime. It would be impossible to cover all of the many topics that fall under the label of 'international' and 'comparative' criminology, so for further reference please refer Section See also at the end of this article.

Comparing Crime across Countries

When comparing crime across countries, criminologists face two major roadblocks: the variation in legal definitions and recording, and the potential inaccuracy of reported rates. In general, it is well understood that most crimes are not comparable across borders due to fluctuations in official reporting practices and legal definitions (Neapolitan, 1997). Only homicide is comparable across countries, and this is because definitions of murder are generally historically and internationally consistent (Marshall and Block, 2004). Even so, international organizations such as the United Nations Office on Drugs and Crime (UNODC) must take special care to ensure homicide data collected from countries are comparable.

The European Sourcebook of Crime and Criminal Justice Statistics 3rd Edition (Aebi, 2006) provides detailed information on the contents of legal definitions of common crimes across 35 countries. The *Sourcebook* shows how hazardous cross-country crime comparisons are, even among countries with shared sociocultural histories. **Table 1** illustrates the differences in legal definitions of robbery and intentional homicide in seven former Soviet Republics. In order to compare robbery rates in Ukraine to those in neighboring Moldova, one must take into account inflation in Moldova due to the inclusion of muggings and pick-pocketing in the reported rates. From **Table 1** it is clear that comparing thefts across countries can be very difficult. In Armenia, burglaries are not explicitly defined in the criminal code, and so are classed as either thefts or robberies (Aebi, 2006). Moldova is the only country that includes embezzlement in the overall amount of thefts. Ukraine has the most restrictive definition of theft, including only burglaries and thefts of other items. Even considering that Lithuania, Estonia, and Russia have similar definitions, both Estonia and Lithuania have slight differences in what kinds of theft are included or excluded. Lithuania, for example, separates general theft apart

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45063-4

Table 1 Differences in legal definitions of robbery and theft in post-soviet countries

Country	Included in robbery definition
Armenia, Estonia, Georgia, Lithuania, Russia	Muggings, theft involving violence
Moldova	Muggings, theft involving violence, pick-pocketing
Ukraine	Theft involving violence
Country	**Included in theft definition**
Armenia, Georgia	Burglary, theft of motor vehicle, theft of other items, theft of small value
Lithuania, Estonia, Russia	Burglary, theft of motor vehicle, theft of other items
Moldova	Burglary, theft of other items, theft of small value, embezzlement
Ukraine	Burglary, theft of other items

Note: In Armenia, burglary is not defined in the criminal code, and so what are classed as burglaries (i.e., "gaining access to a closed part of a building or other premises by use of force with the objective to steal") are counted as robberies or thefts. (Aebi, M.F., 2006. Raw Data for the 3rd Edition (2006) of the European Sourcebook of Crime and Criminal Justice Statistics 2000–2003, p. 25. http://www.europeansourcebook.org/ (accessed 16.03.13.).). In Estonia, theft of small value is included in total thefts only when it occurs during a burglary (p. 27). In Lithuania, certain types of theft are considered separate crimes, e.g., thefts of drugs, guns, or explosives (p. 31).
Source: European Sourcebook for Crime and Criminal Justice Statistics (Aebi, M.F., 2006. Raw Data for the 3rd Edition (2006) of the European Sourcebook of Crime and Criminal Justice Statistics 2000–2003. http://www.europeansourcebook.org/ (accessed 16.03.13.).)

from thefts of guns, drugs, or explosives, and has decriminalized simple thefts up to 125 Lithuanian litas (US $47) (Aebi, 2006: p. 31).

In addition to varying legal definitions, international crime statistics may be inaccurate due to a country's weak institutional capacity to detect and record crimes, or a political interest to make the country appear safer and the state more effective. Before 1989, for example, many researchers believed crime rates in Soviet states were significantly lower than in Western Europe (see Stamatel, 2008). This was in part due to ideological propaganda by Communist political leaders, and partly due to the idea that crime was strictly and forcefully suppressed (Shelley, 1981). On the contrary, Stamatel (2008) found that homicide rates were at least as high as in Western European countries and the United States prior to 1989. The increases in crime after this period that were commonly attributed to transition and democratization were already on the rise before the fall of communism.

In order to avoid these roadblocks, researchers can draw from a range of alternative statistical sources, including victimization surveys, self-reported delinquency studies, and public health data. Victimization surveys, such as the International Crime Victims Survey, aim to capture the number of crimes committed in each country by interviewing a sample of citizens and asking if they have been the victim of a crime in the past 6–12 months (Van Dijk, 2012/2013). Self-reported delinquency studies are more commonly carried out in a single international setting, and while these studies are informative for examining universal predictors of crime, they are not always comparable across countries. However, the second International Self-Reported Delinquency study (ISRD-2) (Junger-Tas et al., 2012b) was carried out in 31 countries to create internationally comparable statistics on crime prevalence and victimization among youth. Finally, public health data are available for lethal violence across a large sample of countries from the World Health Organization (2012). The benefits of public health data are that reporting does not depend on police practices and political motives, and that the definition of lethal violence is based on the standardized International Classification of Disease Codes (ICD). The ICD-10 (10th Revision) defines homicide as "injuries inflicted by another person with intent to injure or kill, by any means" and excludes injuries due to legal intervention and war (World Health Organization, 2010).

Determinants of Crime across Countries

International and comparative investigations of criminological risk factors tend to fall into two broad categories: large-scale cross-national studies and individual-level single- or multisite studies. Both aim to test whether theories and causal risk factors of crime are universal or culturally specific.

Macrolevel Correlates of Crime

Cross-national criminological research has shown a diversity of interests including economic development, modernization, culture, political organization, human rights, punishment, and population structure. Researchers have been gradually expanding the temporal and geographical domain of comparative criminology with the emergence of more and improved international data. Recent research syntheses show that the strongest correlates of national-level homicide rates are income inequality, poverty, human development, and population heterogeneity (Nivette, 2011; Pridemore and Trent, 2010). **Table 2** shows the top 10 strongest indicators of homicide that have been tested in more than 10 studies between the years 1960 and 2010 (see Nivette, 2011). The strongest average effects, as measured by the standardized correlation coefficient (β), come from measures of income inequality ($\beta = .22$–$.48$), as well as measures of family and social structure such as the divorce rate ($\beta = .28$), female labor force participation ($\beta = .22$), and ethnic heterogeneity ($\beta = .22$).

Table 2 Top ten cross-national indicators of homicide with more than 10 contributing studies

Indicator	*No. of studies*	*Average effect size (β)*
Income inequality (ratio top/bottom wealth percentiles)	13	.42
Divorce rate	10	.28
Income inequality (Gini index)	31	.22
Female labor force participation	13	.22
Ethnic heterogeneity	13	.22
Population aged >15 years	17	.12
Development index	14	−.16
Urbanism	27	−.10
Sex ratio (males to females)	15	−.10
Social support	15	−.07

Source: Nivette, A., 2011. Cross-national predictors of crime: a meta-analysis. Homicide Studies 15, 116.

However, Nivette and Pridemore, and Trent have reservations about the conclusiveness and reliability of cross-national results. National-level risk factors are often given little theoretical and methodological attention, and countries are frequently included on the basis of available data rather than theoretical purpose.

One example is the positive link between income inequality (most often measured by the Gini index) and homicide rates. It is clear from a multitude of studies that measures of income inequality are associated with homicide, but one has yet to firmly grasp specifically why, how, and where inequality is detrimental. Indeed, a number of scholars have questioned the inequality–homicide link on both theoretical (Chamlin and Cochran, 2005) and methodological (Pridemore, 2008) grounds. Chamlin and Cochran argued that income stratification is not inherently damaging to social institutions and social relations unless it is founded on ascribed characteristics. When inequalities are ascribed, individuals perceive economic institutions as illegitimate and subsequently withdraw participation and commitment from institutions that provide social control. As such, common explanations for the effects of inequality that are based on psychological strain may be misguided, and any measures that do not distinguish between meritocratic and ascribed inequalities may have low concept validity. Pridemore (2008) argued that the inequality–homicide link is only prevalent due to model misspecification. Specifically, he questioned the absence of indicators of poverty in cross-national research, and attempted to replicate prior studies after including a proxy for poverty (the infant mortality rate). He found that in two of the three studies he reexamined, the inequality–homicide link disappeared when poverty was added to the model.

In order to rigorously test macrolevel theories and risk factors, such as the inequality–crime link, cross-national researchers require larger and more diverse samples along with clear and testable mechanisms connecting the indicator to the outcome. Despite these limitations, however, macrolevel comparative criminology has advanced our understanding of the causes and consequences of criminal behavior within and across a variety of cultural and national contexts. In Stamatel's (2009: p. 18) words,

> Because cross-national research asks fundamentally different research questions, emphasizes macro-level conditions and processes, and makes time and place central to its inquiry, it is well positioned to make unique contributions to both the breadth and depth of knowledge in criminology. Not only are contributions valuable in their own right, but they can also be applied to intra-national research questions, like crime changes in the United States, and they can inform pressing contemporary crime problems, such as terrorism and other transnational crimes.

Microlevel Correlates of Crime

Comparative microlevel studies of crime typically examine the effects of individual, family, school, or neighborhood causal risk factors on criminal behaviors. According to Murray et al. (2009: p. 3), "[r]isk factors are correlates that are shown to predict delinquency. To demonstrate something is a risk factor, a study needs to demonstrate correlations, and the variable be shown to predict the outcome." Despite a growing number of international studies searching for universal or culturally specific risk factors, there is still little conclusive evidence supporting one or the other (Eisner and Nivette, 2012).

Certain theories, such as Gottfredson and Hirschi's (1990) general theory of crime, are explicitly framed as universal theories, essentially rejecting the idea that macrolevel structural and cultural factors play a role in causing crime. A universal risk factor, like Gottfredson and Hirschi's self-control, is expected to predict crime by the same mechanism across all situations and contexts. A culturally specific risk factor, such as the concept of 'machismo' in Latin America (Neapolitan, 1994), is one that is defined by the context in which it operates, including the cultural values, situational contexts, and structural factors that determine the effect of the risk factor on crime (Karstedt, 2001).

Some risk factors have strong international support. For instance, low self-control has been shown to be a robust correlate of criminal and other problem behaviors both in the United States and cross-nationally (Rebellon et al., 2008). Rebellon et al. (2008) examined the salience of self-control on self-reported property crime and violent crime using the International Dating Violence Study (IDVS). The IDVS sampled over 20 000 university students across 32 countries, measuring a range of potential individual and social risk factors. They found that while low self-control proved to be a significant risk factor across all nations, there is evidence that individual self-control is conditioned by the macrolevel context of parental neglect.

The ISRD-2 was designed by Junger-Tas et al. (2012b) to generate comparable measures of self-reported offending and associated risk factors across 31 countries. The ISRD-2 measures a range of individual and social risk factors associated with social control, self-control, opportunity/routine activity theory, and social disorganization. So far, support for these concepts has been mixed. Generally, Junger-Tas et al. (2012a) report that certain risk factors related to the above concepts are relevant across all 31 countries, but not all. In relation to social control theory, Junger-Tas et al. (2012a) found that only measures of family bonding and parental supervision were related to delinquency in the ISRD-2 study. Gatti et al. (2011) found that associating with deviant peers is positively related to delinquency and substance use across all countries. Junger-Tas et al. (2012b) found that school-related risk factors, including school disorganization, truancy, and school bonding, were important correlates of delinquency. Additionally, Steketee et al. (2013) report that perceptions of neighborhood disorganization, individual low self-control, and positive attitudes toward violence all significantly increased the likelihood of delinquency across all countries.

Drawing from a multiethnic sample in Zurich, Switzerland (N = 1229), Ribeaud and Eisner (2010) examined a wide range of cognitive, personal, familial, social, and contextual risk factors on adolescent delinquency. The strength of the Zurich sample is in its sample composition: almost half of the children in the sample (46%) have parents born outside Switzerland. Additionally, parents immigrated from a diverse range of countries, including Germany, Croatia, Serbia, Turkey, and Sri Lanka.

Ribeaud and Eisner found that individual, parental, social, and school risk factors were significantly related to delinquency, whereas parental socioeconomic characteristics were

not. Significant cumulative risk factors include externalizing and internalizing aggressive behaviors (e.g., aggression, attention-deficit hyperactivity disorder), perinatal factors (e.g., maternal depression), internal individual factors (e.g., self-control, sensation-seeking), indoor leisure activities (e.g., extended TV exposure), family structure (e.g., broken home), parenting factors (e.g., lack of parental involvement, use of corporal punishment), school environment (e.g., school disorder), and peer status (e.g., low popularity, low trustworthiness). Sociodemographic characteristics of the parents, such as low parental education, low socioeconomic background, and whether or not the parent was a migrant, were not associated with adolescent delinquency.

Regional Characteristics of Crime

As comparative criminological research expands to every corner of the world, one is gaining a better understanding of levels and characteristics of crime across regions. Macrolevel research has identified regions that tend to share certain characteristics and trends of crime, such as high homicide rates in Latin America, low homicide rates in East Asia, or the convergence of crime rates in Western and Eastern Europe (Gruszczyńska and Heiskanen, 2011; Nivette, 2011; Ouimet, 2012). This section reviews new and unique global and regional research on trends, risk factors, and types of crime in order to demonstrate the wide range of topics concerning comparative criminologists. In addition, it is possible to highlight some potential common characteristics, risk factors, and consequences of crime across such diverse social, political, cultural, and economic contexts.

Table 3 provides a summary of total and gender-specific homicide rates (i.e., violent deaths per 100 000 persons) across eight broad geographical regions in 2008 (World Health Organization, 2012). The lowest homicide rates can be found in Europe ($M = 2.8$), Oceania ($M = 3.3$), and Central and Western Asian countries ($M = 3.8$), whereas the highest are on average found in sub-Saharan Africa ($M = 18.6$) and Central and South America ($M = 21.2$). On average, males across the globe are victimized by fatal violence more than females ($M_{\text{males}} = 15.7$; $M_{\text{females}} = 3.2$).

However, these global estimates must be considered with caution. The extent of uncertainty in certain regions is evident by the variation in the percentage of poor data quality. In many African and Asian countries, information on cause of death is unavailable, meaning the World Health Organization must estimate the number of deaths due to violence using country-specific information and death registration data from other countries in the region (WHO, 2012). For regions with widespread missing data such as Africa, this means homicide rates are based on very few available cases, and as such are likely to be unreliable. This unreliability is apparent in some countries more than others. For example, the World Health Organization estimated a homicide rate of 1.5 deaths per 100 000 persons in Somalia, a complex country that has been plagued by clan-based violence, state collapse, and invasion since 1988 (Linke and Raleigh, 2011).

In Europe, trends in homicide leading up to and following the Second World War are largely described by convergence (Eisner, 2008; Gruszczyńska and Heiskanen, 2011). Eisner (2008) reported that shortly after the Second World War, homicide levels in Western Europe were the lowest in European history (ranging from around 0.2 per 100 000 in the Netherlands in 1957, excluding infanticides, to 0.97 per 100 000 in Austria in 1966). These trends remained relatively similar as homicide increased in the late 1950s and 1960s, peaking in the 1990s and returning to hover around 1 death per 100 000 persons (Eisner, 2008; see also Marshall and Summers, 2012). The fact that the increases and subsequent declines occurred across Western European states (as well as the United States and Canada; see Zimring, 2007) suggests some similar underlying cause. Zimring (2007) argued that it was a number of factors, e.g., the decrease in number of young males, expanding welfare policy, increases in police numbers, and incarceration, that led to the 'great American crime decline' in the 1990s. However, he admitted these changes did not occur in Canada, where a similar crime trend was observed, and differences in policy and social structure are even more acute between Western Europe and the United States.

Within Europe, there are, however, several points of divergence. After 1989, crime and violence increased dramatically among postcommunist states, but more recently show decline and stability (Andresen, 2011; Marshall and Summers, 2012). Certain postcommunist states still have relatively higher levels of violence, particularly the Baltic region (i.e., Latvia, Lithuania, and Estonia), with an average of 10 deaths per 100 000 persons

Table 3 Average homicide rates (deaths by violence per 100 000 persons) in 2008 by gender across eight geographical regions

Region	*No. of countries*	*Average total rate*	*Average male rate*	*Average female rate*	*Percentage of poor data*
Europe	42	2.8	4.2	1.5	0.05%
Oceania	16	3.3	4.3	2.2	50%
Central & Western Asia	22	3.8	6.2	1.5	27%
Southern & East Asia	25	5.8	9.8	1.8	48%
Northern Africa	6	6.1	8.6	3.7	83%
North America & Caribbean	15	13.7	24.3	3.3	0%
Sub-Saharan Africa	47	18.6	30.5	7.0	94%
Central & South America	20	21.2	38.0	4.8	10%
Total	193	9.4	15.7	3.2	39%

Note: The percentage of poor data was calculated as the percentage of countries in the region where most data for cause of death were unavailable, meaning rates were estimated by the World Health Organization using country-specific information and cause of death patterns from other countries in the region.

for the period 1990–2008 (Marshall and Summers, 2012: p. 59). Gruszczyńska (2004) pointed out that since independence in 1989, some postcommunist states have become 'corridors' for drug trafficking, car theft, and the expansion of organized crime rings between east and west. The problem has only intensified since Latvia, Lithuania, and Estonia gained membership to the European Union, requiring these states to more actively police their borders with Russia and Belarus (Ceccato, 2008; Gruszczyńska, 2004).

The UNODC's *Global Study on Homicide 2011* provides detailed information on the weapons used, age of the offender and the victim, and circumstances surrounding the murder where data are available. UNODC (2011: p. 40) reports that firearms are used to commit homicide more frequently in the Americas than in Europe. The percentage of homicide cases in 2008 involving a firearm ranged from about 6% in Eastern Europe to over 70% in South America. In Europe, homicides were more frequently committed using a sharp object, such as a knife.

Although data are sparse for most African countries, the *Global Burden of Armed Violence 2011* reports that in South Africa, "firearm homicide has been singled out as the leading cause of death for young men aged 15–21" (Geneva Declaration Secretariat, 2011: p. 162, citation omitted). Pierre du Toit (2001) argued that the resistance to apartheid, coupled with recent civil wars in the region, contributed to the proliferation and flow of arms in South Africa. While this may contribute to South Africa's high firearm homicide rates, the *Global Burden of Armed Violence* also implicates high levels of income inequality, unemployment, and poverty.

In sub-Saharan Africa, the rate of lethal violence and the persistence of civil conflict are often highly correlated (Geneva Declaration Secretariat, 2011). However, the context in which high rates of firearm homicides occur differs in Central and South America. UNODC (2011) reports that high homicide – in particular homicide by firearms – is not entirely attributable to conflict in Latin America and the Caribbean regions. Instead, firearm homicide is associated with organized crime and gang activity. Importantly, they are clear that organized crime/gangs are not necessarily the cause of high rates: "many countries in the region were vulnerable to crime and violence for a number of reasons, including their legacy of armed conflicts and violence, the easy availability of guns, chaotic urbanization, high income inequality, a high proportion of youth, local gang structures, as well as organized crime and drug trafficking" (UNODC, 2011: p. 49).

National-level rates can often mask gang-related intrastate variation, as in the case of Mexico's escalating drug war. Mexico's overall homicide rate has remained relatively stable from 2004 to 2009 at 11.5 deaths per 100 000 persons (Geneva Declaration Secretariat, 2011). However, in the state of Chihuahua, the homicide rate was 108 per 100 000 in 2009, which the *Global Burden of Armed Violence* attributes to an increase in drug trafficking, organized crime, and confrontations with the Mexican government. In fact, in 2010, 41% of Mexico's homicides occurred in four states: Chihuahua, Sinaloa, Guerrero, and Baja California, which together account for 11% of the total population of Mexico (UNODC, 2011). Furthermore, UNODC (2011) reports that in 2008–09, two-thirds of homicides in Chihuahua occurred in Ciudad Juárez, and three-fourths of homicides in Baja California occurred in Tijuana. This means that the nature of homicide in Mexico – particularly in areas affected by drug cartels – differs significantly from most homicides occurring in Europe, and so researchers must be careful when considering broad cross-national explanations of crime.

Comparative criminology is essential to understanding these transnational organizations and their impact on local social order and crime. International organizations and national governments are increasingly concerned about cross-border criminal activity, such as human, drug, and weapons trafficking; wildlife smuggling; the spread of organized crime syndicates; and terrorism.

For example, since the terrorist attacks in the United States on 11 September 2001, the study of terrorism has become a hot topic in comparative and international criminology. However, until recently, very little was known about the spatial patterns of terrorist activity and associated risk factors (LaFree and Ackerman, 2009; LaFree et al., 2010).

Gary LaFree and Laura Dugan (2007) have improved the comparative study of terrorism by developing a systematic database of both domestic and international terrorist events dating back to 1970. The Global Terrorism Database (GTD) uses media and other open-source databases to compile a comprehensive list of events that include information on the attacker(s), intended target(s), country of origin, country of incident, number of fatalities, number of injuries, weapons used, and intention (e.g., assassination, political protest).

LaFree et al. (2010) examined the trajectory and spatial distribution of terrorist attacks across countries using the GTD. They found that most fatal and nonfatal terrorist attacks since 1970 were clustered in four regions: Latin America (30.43% of all attacks), Western Europe (20.75%), Middle East/Persian Gulf (15.41%), and South Asia (14.45%). Terrorist attacks were least frequent in North America (1.24% of all attacks) and East/Central Asia (1.19%). LaFree et al. (2010: p. 633) point out that Latin America and Western Europe likely have more attacks because of "long-lasting and stable terrorist groups that often claim responsibility for their attacks." For example, in Colombia, the Revolutionary Armed Forces of Colombia have been operating for decades, as have the Basque Fatherland and Freedom in Spain, and the Irish Republican Army in Northern Ireland (Global Terrorism Database, 2013).

Using trajectory analyses, LaFree and his colleagues identified several countries with rapidly rising number of terrorist attacks since 1999, which they characterized as 'hot spots': Afghanistan, Bangladesh, Indonesia, Iraq, Kashmir, Nepal, Rwanda, Thailand, and West Bank/Gaza. However, LaFree et al.'s (2010) analysis of 'hot spots' only includes incidents up to 2006, meaning recent surges in attacks from Islamist group Boko Haram in Nigeria and Al-Shabaab in Somalia and Kenya are not included in LaFree et al.'s analyses (Marchal, 2009; Africa Research Bulletin, 2013). Further, the cases of Boko Haram and Al-Shabaab show the limitations of using incidents of attacks to predict future terrorist attacks. According to the GTD, since 2006, there have been four total attacks attributable to known groups in Rwanda, whereas there have been 205 in Somalia and 159 in Nigeria. (Counts only include attacks that have been attributed to a known perpetrator by the media, meet terrorism criterion 1 (political aim) and 2 (coercive intent), and exclude ambiguous and unsuccessful attacks (see Global Terrorism Database, 2013).) Predicting the success and decline of terrorist groups is understudied in comparative

criminology, but recent research suggests that the size and political/religious ideology of the group contribute to their longevity (LaFree and Ackerman, 2009).

Individual-level research on terrorism has examined a range of possible causes, including psychopathology, personality, trauma and alienation, personal status, moral neutralization, demographics, employment, education, marriage, group-level grievances, and socialization (LaFree and Ackerman, 2009). In their review of potential causes, LaFree and Ackerman find little empirical evidence to support psychopathological perspectives, which propose that terrorists disproportionally suffer from mental disorders, cognitive maladaptations, or other risk factors associated with suicide (in the case of suicide bombers). They found general support for a relationship between individual trauma or alienation and terrorist attitudes and behaviors. They argue that "while not genuinely causal in nature, trauma, perceived injustice, and alienation can be termed facilitative variables in that they may act to make individuals more antagonistic toward outgroups, more vulnerable to terrorist ideologies, or more open to mechanisms of self-justification for the use of violence" (LaFree and Ackerman, 2009: p. 350). While there is evidence that terrorists tend to be young males, other known criminological correlates of crime are not supported by evidence: employment, marriage, parenthood, and education. More generally, they find that comparative research on individual-level causes and correlates of terrorist activities is vastly underresearched.

Comparative and international research is also useful for illuminating the universal and culturally specific dangers women face across the globe. Women are more likely to be killed by a family member or spouse than men in the United States, Israel, Canada, South Africa, Australia, and across Europe (UNODC, 2011). UNODC (2011: p. 58) show that for a selection of European countries, 77% of all victims killed by their spouses or exspouses were women. This suggests that situational risk factors for female victimization are similar across countries; however, the form of victimization may vary.

The *Global Burden of Armed Violence* discusses a number of 'hidden forms' of violence against women, including 'honor killings,' 'dowry deaths,' witchcraft killings, gender-related forced suicide, and genital mutilation. Official data on violence against women likely underestimate the true levels due to underreporting and the 'hidden' nature of domestic violence. Because of this, comparative researchers often rely on secondary sources and media outlets to gain information on the characteristics and levels of 'hidden forms' of violence against women.

For example, although honor killings have existed in many different cultures for centuries, reliable data on honor killings are scarce (Goldstein, 2002). Goldstein argues that the absence of data is possibly due to an unwillingness to report crimes, a lack of legal recognition of honor crimes, and the tendency for honor killings to occur during times of war. Country-level estimates of the number of honor killings range from 400 in Yemen in 1997, to over a 1000 in Pakistan in 1999, to over 5000 worldwide each year (Goldstein, 2002: p. 31). According to the United Nations Commission on Human Rights (see Jahangir, 2000), honor killings have been recorded in a diverse range of countries, including Bangladesh, Ecuador, Great Britain, India, Israel, Jordan, and Turkey.

Sev'er and Yurdakul (2001) used a sample of honor killings reported in the media and by other academics to examine the characteristics of female honor killings in Turkey. The authors (2001: pp. 964–965, citations omitted) define honor killing as "the premeditated murder of preadolescent, adolescent, or adult women by one or more male members of the immediate or extended family." They further describe the circumstances under which honor killings tend to occur in Turkey: "These killings are often undertaken when a family council decides on the time and form of execution due to an allegation, suspicion, or proof of sexual impropriety by the victim" (p. 965). They found that most honor killings occurred in rural populations characterized by low incomes, low education, early marriages, and a 'feudal type of land ownership' that leaves "nothing to the majority of disenfranchised men (except power over women and children)" (Sev'er and Yurdakul, 2001: p. 989).

Survey-based studies of honor killing are rare. However, recently Eisner and Ghuneim (2013) conducted one of the first studies to use psychometric instruments to measure attitudes toward honor killing. Among a convenience sample of 856 ninth graders in Amman, Jordan, the authors found that 46.1% of boys agreed with items stating "It is okay for a man to kill his daughter [sister, wife] if she has dishonored her family" (p. 411). By contrast, only 22.1% of girls supported honor killings. Adolescents who supported honor killings were more likely to come from low education and 'breadwinner'-type families (i.e., mother is a house wife), espouse traditional attitudes (i.e., patriarchal and anti-Western values), believe that females should remain chaste, and rely on moral neutralization techniques to excuse violence more generally (pp. 410–412). The authors conclude that "any meaningful attempt to reduce attitudes in support of honor killings therefore probably requires a broader societal commitment to changing the underlying cultural support for patriarchal dominance, including moral justification of private violence against transgressors" (p. 415).

Conclusion

In sum, geographical and cultural regions face many different challenges to social order, but there are also seemingly common characteristics and risk factors found in different contexts. Across the globe, men are more likely to be the perpetrators and victims of lethal violence, whereas women are more likely to be victims of lethal domestic violence. Certain individual and socioeconomic risk factors of crime, such as moral neutralization, income inequality, poverty, and lack of education are likely related to a range of criminal activities, including honor killing, terrorism, organized crime, and gang violence. Finally, crimes tend to be spatially concentrated. Within Europe, crime is generally higher in Eastern Europe; however, east/west trends are likely to converge, and homicide tends to cluster in Central and South America as well as in sub-Saharan Africa. A review of violence in Mexico revealed that crimes are likely further spatially concentrated within countries. Terrorist attacks are concentrated in Latin America, Western Europe, and the Middle East.

Although this suggests criminal behaviors have some common roots across countries, more comparative and

international research is needed to explore universal and culturally specific risk factors and contexts of crime. It is important to remember that universality and cultural relativism are not inherently antagonistic to each other. In Karstedt's (2001: p. 302) words,

> we should shift our perspective systematically from differences toward universals and vice versa. Indigenization does not imply that universals or a universal theory are useless, but to the contrary: It directs attention to the culture-bound quality of those theories that we rate as universal theories, or directs the search toward hitherto neglected and potential universals. Any such tendencies toward such dichotomies are inimical to the development of the discipline.

What comparative and international criminology makes clear is that "we are a criminally challenged planet" (Adler, 1996: p. 3). While there are many methodological and theoretical problems to overcome, comparative research is nevertheless imperative to our understanding of crime.

International Arbitration

Bryant G Garth, University of California, Irvine, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article defines international arbitration, distinguishing between state–state arbitration, international commercial arbitration, and investment arbitration. It shows how international commercial arbitration became the default dispute resolution mechanism for transnational commercial disputes in the 1980s, and how the field has prospered since that period. The article relates international commercial arbitration to the alternative dispute resolution movement, and it concludes with a discussion of how one gets to be an arbitrator trusted to handle very high-stakes commercial disputes.

'International arbitration' refers to the private mechanisms for resolving either disputes between states or transnational business disputes. Since the 1960s, the system of international commercial arbitration has grown dramatically in importance, becoming the default dispute resolution device provided for in international commercial contracts. There is a relatively small group of international commercial arbitrators who handle most of the significant cases. The system began as a relatively informal system, close to the procedures of the European Continent. It has greatly expanded, due to the rise of trade and the increasing legitimization of this system around the world. With this expansion, the system has become much more adversarial, contested, and document intensive, due in part to the pressures of US litigators who are playing a larger role in the procedures. International commercial arbitration involves hundreds of international commercial arbitration centers competing to have the most prominent rosters of arbitrators and the largest number of high-stakes international cases, but the leading organization has long been the International Chamber of Commerce (ICC) in Paris. International arbitration can be used to resolve commercial disputes, disputes between business entities and states, or disputes between states. Arbitration procedures for disputes between states, exemplified by disputes about borders, are ad hoc and infrequently invoked. Of much more practical relevance since the 1980s is the system of private justice created to resolve international business disputes, which has become the standard system for international transactions. When two businesses with headquarters in different countries enter into a contractual arrangement, the contract will generally provide that any disputes relating to the contract will be resolved through private arbitration.

Since the 1990s, in addition, there have been increasing numbers of investment arbitrations created under treaties such as the North American Free Trade Agreement and the proliferating number of Bilateral Investment Treaties (BIT) – estimated now at close to 3000. Disputes between investing countries and host states governed by a BIT are typically referred to the International Center for Settlement of Investment Disputes (ICSID) operated under the auspices of the World Bank. The arbitrators who handle ICSID disputes are in general the same ones who staff the major international commercial arbitrations.

The number of international commercial arbitrations is impossible to determine precisely since many of the arbitrations are not administered by any formal organization, and there is no clear line between domestic and international. International commercial arbitration may be institutional, under the auspices of one of the institutions competing for the business of international commercial arbitration, or it may be ad hoc, handled solely by the parties and their counsel. It is especially difficult to count the ad hoc arbitrations.

It is clear, however, that the number of international commercial arbitrations has been increasing generally and in relation to the global financial crisis that began in 2008. The most important of the institutions is the ICC in Paris, France, and it generally has the largest caseload and the cases involving the highest stakes. In 2011, some 796 requests for arbitration were filed with the ICC, concerning 2293 parties from 139 different countries. The places of arbitration assigned to the cases involved 63 different countries on 5 continents. Arbitrators of 78 different nationalities were appointed or confirmed under the ICC Rules, and the amount in controversy exceeded US$1 million in 77% of the new cases. The ICC Court, which confirms the awards, had 508 new awards submitted in that year.

In addition to the ICC in Paris, other leading centers are the London Court of International Commercial Arbitration, the American Arbitration Association, the Chinese International Economic and Trade Arbitration Commission, the Hong Kong International Arbitration Center, the Singapore International Arbitration Center, the Korean Commercial Arbitration Board, the Japan Commercial Arbitration Association, and the Stockholm Chamber of Commerce. As noted above, ICSID is the major institution for investment arbitration. The ICC is especially useful for relatively new participants to international commercial arbitration. The ICC, while more expensive, helps to guide new parties and new arbitrators through the processes, and it also has a reputation as an institution that can ensure that its awards are respected in domestic courts.

International commercial arbitration – as arbitration generally – involves a process whereby a third party issues an opinion that is formally binding on the parties. Unlike domestic arbitration (as it has traditionally been practiced in the United States), international commercial arbitrators typically write formal opinions. These formal opinions typically are

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86039-0

neither published nor made public informally. They belong to the parties, who must therefore consent to any publication. The awards made by the arbitrators are binding and very difficult to challenge or appeal. The New York Convention of 1958, which has been adopted by well over 100 states, makes an arbitral award in practice more easily enforced within a contracting state than would be a judgment obtained through litigation. In addition, the procedures of international commercial arbitration have been converging around a set of rules that tend to detach arbitration from its site and to emphasize party autonomy. The United Nations Commission on International Trade Law model law has been the major model for this convergence.

The most prominent feature of international arbitration is that the arbitrators are private individuals without any formal connection to the state or a state judicial system. In theory, almost anyone could be selected as an arbitrator. In practice, however, there is a relatively small group that tends to dominate selection for major arbitrations. The group consists largely of European lawyers, professors, and retired judges, but there are also prominent arbitrators from other parts of the world.

The advantages of arbitration in international disputes are usually listed as follows: the ability to select elite private judges, the secrecy of the proceedings, and the ability to avoid having to submit to the judicial system of the opposing party. Not generally listed as advantages are the cost and the duration of the proceedings, since in fact arbitrations may cost as much as or more, and take as much as or more time, than litigation in a national court system.

A number of interesting sociolegal issues relate to international commercial arbitration. They include (1) how this system of private justice came to be considered the legitimate way to resolve international business disputes, (2) what this system means for issues concerned with alternative dispute resolution more generally, and (3) how people become international commercial arbitrators.

Building the International Arbitration System

International business was long a world of complex personal relations rather than formal laws and dispute resolution processes. The number of actors was relatively small in any given field, and the actors could get to know and take account of each other. There might be contracts, but the contracts were relatively unimportant documents either in the negotiation or when disputes might arise. Histories of the petroleum industry, in particular, reveal the key actors behind the 'seven sister' oil companies and how they interacted with the countries in which they did business. Lawyers were very much part of this history, but lawyers for the oil companies – including John McCloy, the famous lawyer for the Rockefeller family who was termed the 'chairman of the establishment' – relied much more on personal influence and connections than on their expertise as lawyers.

When this relatively stable set of relationships was shaken up, especially by new entrants in the 1960s and 1970s willing to offer more favorable terms to produce the oil, the lawyers for the oil companies used contract and international law to try to hold on to their privileged positions. At the same time, a small number of elite actors in the exporting countries had taken advantage of oil company paternalism to obtain education abroad – in law and engineering, for example. They and a few maverick legal advisors began to formulate legal arguments that slowly built the legal infrastructure of the industry. The major transformation of dispute resolution, however, followed the nationalization of the oil industries in most of the oil-exporting countries. The oil concession agreements typically had arbitration clauses, because arbitration had long been practiced in disputes between nations. When the oil industry was nationalized in places such as Kuwait, Libya, and Saudi Arabia, the companies invoked the arbitration clauses and began arbitration processes.

Legal accounts of this period typically celebrate the grand arbitrations that resulted, suggesting that important legal principles supporting the stability of contracts trumped the political acts of nationalization. Other accounts, including those by journalists and historians, however, do not mention the arbitrations at all. They instead emphasize the negotiations that took place between those who had long invested in the relationships, the negotiations between governmental actors at another level, and the gunboats that were exerting not-so-subtle pressure on behalf of the oil companies. Lawyers involved at the time suggest that their activity in the arbitrations was not highly valued or even much noticed by company executives.

The arbitration processes did go forward, however, and they produced raw material that equipped international business with people and principles to handle transnational disputes. The raw material was in the form of written opinions that were widely circulated, academic articles about the principles in the opinions, and individuals who gained or enhanced their reputations as potential arbitrators by virtue of their participation in the arbitrations. The petroleum arbitrations thus contributed to the production and legitimization of international commercial arbitration for transnational business disputes.

When new sets of problems arose that related to some of the themes of the petroleum arbitrations, in particular disputes involving the numerous construction projects that took place in oil-producing countries after the price of oil increased in the early 1970s, international commercial arbitration played a crucial role. The Continental academics who developed these principles into a new *lex mercatoria* also developed relationships with students from the less developed world, and the students helped to reinforce the legitimacy of these principles in their own countries. Put very simply, the process produced lawyers on both sides, legal principles, and a legitimacy that made it possible to generate a demand for what this group supplied. For the ICC, this increased demand meant that while the first 3000 requests for arbitration came between 1923 and 1976, the next 3000 came in the following 11 years.

International Commercial Arbitration and Alternative Dispute Resolution

The world of international commercial arbitration was dominated in the 1960s and 1970s by Continental academics who wrote about the *lex mercatoria*, and by arbitrators who

encouraged the parties to find a way to settle the dispute. The *lex mercatoria* could be used by the arbitrators to find a solution that fit the business relationship and left the parties satisfied with the result. Consistent with the general orientation of the leading arbitrators and lawyers associated with the pioneers of international commercial arbitration, the process was not very adversarial, was relatively inexpensive except for the arbitrators, did not tend to produce extensive documentary evidence, and did not contemplate such US practices as cross-examination of witnesses. The model was quite consistent with Continental practices, even when non-European actors participated in the processes.

When the arbitration business began to take off in the 1970s and 1980s, it coincided with the rise of business litigation in the United States. The US law firms in Paris, France, were long involved in international commercial arbitration, but they tended to play according to the Continental rules. As the practice of international commercial arbitration grew and expanded outside of a relatively small circle of people, US businesses became increasingly involved in arbitration, and developing countries found it to be in their interests to hire US law firms as well. The enhanced presence of US litigators had important consequences. They naturally sought to use the techniques of discovery, intensive production of documents, cross-examination of witnesses, and more generally the kind of aggressive adversarial behavior that was beginning to characterize litigation in the United States. They also sought to retain arbitrators who would permit the lawyers to use the techniques that they had developed. The result was that the processes of international commercial arbitration changed substantially. They did not become identical to US litigation proceedings, but they moved much closer to US adversarialism. International commercial arbitration became much more document intensive, much more adversarial, and much more expensive.

Litigation in the United States had also been transformed, and that transformation had produced the beginnings of the alternative dispute resolution movement in that country. New organizations such as the Center for Public Resources had begun to encourage corporations to practice more mediation as a way to avoid the high costs and adversarial nature of business litigation. The movement became quite influential in the United States, and some of the individuals associated with it began to suggest that it would also be useful for international commercial arbitration. Not surprisingly, the first reaction of many within the international arbitration community was that they already practiced mediation as part of the normal process. They argued that the practice of international arbitration provided an effective alternative to litigation as practiced in the United States.

As international commercial arbitration became more like US litigation, however, the US-promoted alternative began to gain more adherents within the international arbitration community. By the end of the twentieth century, the menu of US alternatives – including mediation but a range of others as well – had become much more common. This gradual transformation illustrates the way that the formal categories of dispute resolution – litigation, arbitration, and even mediation – can disguise profound transformations in the way that the underlying practices proceed. The center of gravity of international commercial arbitration moved much closer to US-style litigation, which was itself a relatively new invention, and the shift also helped to bring the US antidote, alternative dispute resolution.

Becoming an Arbitrator

The international commercial arbitration community is relatively closed, and it is often termed a 'mafia' even by insiders. One reason for this 'club' is simply that for high-stakes arbitration, the parties typically want to select arbitrators who are known quantities. Untested arbitrators are very risky from the point of view of the parties. It is also deemed important to select arbitrators who are known for their ability to 'speak the language' and be taken seriously within an arbitral tribunal. Since arbitrators often serve as counsel because of their familiarity with the processes and people, it is common for people from the relatively closed arbitral community to nominate others from the community. The key to success in the arbitration proceeding is selecting an arbitrator who will be impartial enough to persuade the chair of the tribunal but also able to understand and put forward the case of the party that appointed him or her. The selection of established names also serves a protective function in case the decision does not favor the selecting party. It is easier to avoid blame for a safe selection than for a novel one. For many reasons, including the fact that a relatively small supply serves the economic interests of the arbitrators, it is not easy to gain entrance into this community.

The easiest way to gain entrance for at least some small cases that may provide a basis to build a practice is to conform to the characteristics of those already in the field. The individuals who set the norms emphasized scholarly accomplishments, which put an emphasis on publications, cosmopolitanism, and linguistic ability. Those who seek to enter must probably also attend a number of the major conferences in order to display the appropriate characteristics and be judged more personally. However, the general point is that invitations to enter the community tend to be issued most easily to those who can offer something to the existing community – most obviously persons of high status who reflect that status back on the arbitral community, persons from areas that are not yet committed to the legitimacy of international commercial arbitration (which means they offer both credibility and a potential new caseload), or sometimes disciples of those already in the arbitral community. This process helps to explain why individuals without high status may study, write, and attend conferences, but lacking a prestigious platform, they cannot gain entry. On the other hand, individuals from developing countries who serve as judges on the World Court do typically gain entry. The process also helps explain why there are so many arbitration centers despite the fact that the caseloads are concentrated in a relatively few places. Those who create new centers gain the attention of the elite of the arbitral community and also help to provide new domains where businesses will contemplate arbitration and courts will respect the awards. As a result, the new center may promote the local leader into a position closer to the core of the arbitral community. There tend to be relatively few of these peripheral arbitrators in each relevant site.

International arbitration, especially through commercial contracts and investment treaties, is thriving today and has

been steadily gaining importance in new terrains that were once resistant to arbitration, such as Latin America. The arbitration community is still relatively small, but it has evolved and gained legitimacy through the addition of at least a small number of arbitrators from outside the major capitals of the global North.

Abstract

Founded in 1928, the International Association of Schools of Social Work is the worldwide organization representing social work education. Comprising member schools and individuals across all continents, it works, in spite of funding and voluntary leadership challenges, to create a globally inclusive organization and promote curriculum development, research, and international exchanges.

Brief Overview

The International Association of Schools of Social Work (IASSW) is the worldwide association of schools of social work, other tertiary level social work educational programs, and social work educators. The IASSW promotes the development of social work education throughout the world, develops standards to enhance quality of social work education, encourages international exchanges, provides forums for sharing social work research and scholarship, and promotes human rights and social development through policy and advocacy activities (IASSW, 2013).

Membership in the IASSW comprises social work educational programs at the postsecondary or tertiary level and interested individuals, mostly social work educators. The Association has member schools in all parts of the world: five regional organizations in Africa, Asia and the Pacific, Europe, Latin America, and North America and the Caribbean; and three subregional associations – the Nordic subregion, the Caribbean subregion, and Eastern European subregion are affiliated with the IASSW. IASSW is governed by the Board of Directors under a Constitution approved by the biennial General Assembly. IASSW holds and, has held since 1947, consultative status with the United Nations (UN) and participates as a nongovernmental organization (NGO) in UN activities in Geneva, Vienna, and New York and other parts of the world. Through its work at the UN and with other international organizations, IASSW represents social work education at the international level.

According to Tasse (2008), some of the key features of the IASSW include: developing visions of the profession that enable it to rise to meet major challenges at critical point of history; articulating the voice of the profession in key international institutions and forums; disseminating best practices in the profession through social work education; and promoting international and comparative research.

The IASSW was founded in 1928 and is one of the largest and oldest social work professional organizations. It is a membership organization based on voluntary commitments. Over the years, IASSW has experienced turmoil caused by the expulsion of its first president by the Nazi regime in Germany, World War II, the termination of social work programs in Eastern Europe and China under Communism, internal disputes over the proper course of action in dealing with apartheid South Africa, and financial difficulties that resulted in the loss of a secretary-general and secretariat in the early 1990s. Through it all, however, under the leadership of its Presidents and Board, IASSW has remained engaged in its core purposes of promoting and representing social work education through international exchanges and advocacy. This history augurs well for the future of social work education.

IASSW Mission

The mission statement adopted in 2000 commits the IASSW as the international organization to four major purposes: (1) to develop and promote worldwide excellence in social work education, research and scholarship in order to enhance human well-being; (2) to create and maintain a dynamic community of social work educators and their programs; (3) to support and facilitate participation in mutual exchanges of information and expertise; and (4) to represent social work education at the international level.

In fulfilling its mission, members adhere to all UN Declarations and Conventions on human rights, and recognize that respect for the inalienable rights of the individual is the foundation of freedom, justice, and peace. Additionally IASSW fosters cooperation, collegiality, and interdependence among members and with others, engages in the pursuit of social justice and social development.

The IASSW carries out its mission through:

- developing global standards; and other documents including the ethics document and international definition of social work in collaboration with the International Federation of Social Workers (IFSW);
- organizing conferences for social work educators;
- organizing training programs and curriculum consultations;
- publications and usage of social media;
- representation at the UN;
- activities of Committees and Task Forces;

- funding of cross-national projects in social work education; and
- collaborating with other international social work organizations.

IASSW Current Membership

Currently, the IASSW has both school/social work program memberships and individual memberships. School membership is open to tertiary level education programs that prepare students for the profession of social work. Individual membership is open to any social work educator or other persons interested in social work education. Members of all categories must, to the best of their ability, safeguard the interests of the IASSW, pay the stipulated dues and act in accordance with the by-laws and resolutions of the IASSW which include abiding by UN Conventions on human rights, children, women, and others linked to the equal rights of minority ethnic groups, indigenous peoples, and disabled people among others.

Members of the IASSW have rights to:

- participation in ongoing projects related to social themes – poverty, macrodevelopment, peace, and human rights, ecology, women, children, AIDS and others, as well as activities of the IASSW committees and task forces;
- reduced registration fee at biennial international congresses organized by the IASSW;
- free subscription to the IASSW Listserve and *Social Dialogue* magazine;
- free subscription to *International Social Work* journal (for IASSW individual members) and discounted subscription to *International Journal of Social Welfare* (for IASSW individual members); and
- accessibility to IASSW funding regarding joint projects with other schools of social work, designed to advance IASSW Mission and to the enhancement of cooperation among schools of social work worldwide.

Each school has a vote at the General Assembly held biennially. Individual members have the same privileges as mentioned above and a prorata right to vote at the General Assembly.

IASSW has around 500 members from 62 countries. Its largest member schools are from Japan, China, and the United States. The membership across the regions is as in Figure 1, although this is subject to fluctuations.

IASSW Leadership and Governing Bodies

According to the current IASSW Constitution, the organization is governed by the Board of Directors, made up of both elected and appointed members. The nominating Committee prepares slates of candidates for the biennial elections of officers and at-large board members. Ballots are sent to all members. Regional representation is ensured through the inclusion of five regional vice presidents on the Executive Committee and Board of Directors. Currently, three subregional associations are also

Figure 1 Distribution of 2013 IASSW membership across the regions ($N = 507$).

recognized, and each can elect a member to the Board of Directors: the Association of Caribbean Social Work Educators, the Nordic Association of Schools of Social Work, and East European Association of Schools of Social Work. National associations are entitled to a board representative if the country has at least five IASSW member schools. The Board of Directors carries responsibility for the ongoing direction of the association and development and oversight of the budget.

According to Healy (2008) the leaders of the IASSW have played major roles in shaping the organization over its 80-year history. Starting from 1928 the IASSW had 12 Presidents (see a full list in Table 1).

For more than 50 years they were from Europe, USA, and Canada. This reality is a function of the European/North Atlantic origins and the composition of the organization with the same line of interest for many years. The first President outside of Europe and North America (Abye Tasse from Ethiopia) was elected in 2004.

From 1978 to 2010 the IASSW had a position of the Honorary President. It was occupied by Katherine A. Kendall (USA) who served as the first paid Secretary General of the IASSW in the 1970s and was heavily involved in IASSW activities until her death in 2010 (CSWE, 2013). The position has remained vacant since.

Major policy changes and significant changes to the constitution require action by delegates at the General Assembly, which meets biennially during the world conference. All IASSW members participate in the Assembly, with programs

Table 1 A list of IASSW presidents (1928–2012)

Period	*Name of the president*
1928/29–1946	Alice Salomon (Germany, then – USA)
1946–1953	René Sand (Belgium)
1954–1961	Jan Floris de Jongh (the Netherlands)
1961–1968	Eileena Younghusband (United Kingdom)
1968–1976	Herman D. Stein (USA)
1976–1980	Robin Huws Jones (United Kingdom)
1980–1988	Heiner Schiller (Germany)
1988–1996	Ralph Garber (Canada)
1996–2004	Lena Dominelli (United Kingdom)
2004–2008	Abye Tasse (Ethiopia)
2008–2012	Angelina Yuen (Hong Kong)
2012–2016	Vimla Nadkarni (India)

having one full vote each and individual members having one-tenth of a vote.

Social work educators and practitioners considered professional and educational issues around thematic concerns at its biennial international congresses which were held in: 1928 Paris; 1932 Frankfurt; 1936 London; 1948 Atlantic City; 1950 Paris; 1952 Madras; 1954 Toronto; 1956 Munich; 1958 Tokyo; 1960 Rome; 1962 Brazil; 1964 Athens; 1966 Washington; 1968 Helsinki; 1970 Manila; 1972 The Hague; 1974 Nairobi; 1976 Puerto Rico; 1978 Jerusalem; 1980 Hong Kong; 1982 Brighton; 1984 Montreal; 1986 Tokyo; 1988 Vienna; 1990 Lima; 1992 Washington; 1994 Amsterdam; 1996 Hong Kong; 1998 Jerusalem; 2000 Montreal; 2002 Montpellier; 2004 Adelaide; 2006 Santiago de Chile; 2008 Durban (Seibel, 2008); 2010 Hong Kong; 2012 Stockholm; 2014 Melbourne.

During the congress held in Amsterdam (the Netherlands) in 1994, IASSW changed its constitution and structure to devolve greater powers to its regions.

The biennial international congress in Hong Kong (2010), Stockholm, Sweden (2012), and Melbourne, Australia (2014) were co-organized by IASSW, the IFSW, and the International Council on Social Welfare (ICSW). IASSW shares with these organizations the same purpose of working to increase the voice of the social work profession. Similar arrangements had been in place earlier during the 1992, 1996, and 1998 Congresses. For internal structural reasons, ICSW withdrew from the 2000 tripartite arrangements, and IASSW and IFSW held their joint Congress in Montreal.

Work of the association is furthered through several committees and task forces that are clustered under four major themes: Education, Advocacy, Administration, Budget and Finance. Since 2012, the Education Committees cluster includes capacity building, research, and international projects. The Advocacy Committee cluster covers sustainability, climate change, disaster intervention; communications and publications; human rights and the global agenda. The administration cluster comprises the Nominating Committee, Language Committee, and the Standing Committee on World Census. The IASSW has strong, active lead representatives at the UN.

IASSW Language Policy and Publications

As IASSW is open to all social work educational programs from all over the world, its aim is to practice an inclusive language policy, and refrain from becoming an elite organization dominated only by member institutions from the western world. Language policy and practice is an important factor for deciding whether this is an attractive organization for a global target group.

IASSW has four official languages: English, French, Spanish, and Japanese. These are the languages of the majority number of IASSW member schools. However, English is the dominant one due to both lack of financial and human resources for translations. At one point, IASSW's language policy included Chinese, Russian, and Arabic, but this also proved financially unfeasible and now the seven languages are reflected only in the abstracts for articles in *International Social Work*.

The IASSW is expanding knowledge of international social work through cosponsorship of the journal *International Social Work* (http://isw.sagepub.com) and publishing online magazine 'Social Dialogue' (http://www.social-dialogue.com).

In 2012, Facebook (http://www.facebook.com/IASSW.AIETS) and Twitter (@IASSW-AIETS) official accounts of the IASSW were opened.

IASSW History

The history of the IASSW was studied by Kendall (1978), Healy (2001, 2008), Kniephoff-Knebel and Seibel (2008) and others mainly within the framework of internationalization of social work. Researchers paid special attention to the periodization of the IASSW activities based on mutual respect and non-paternalistic principles and the IASSW leadership.

Seibel (2008) stressed that milestones reflected in the IASSW history were in particular the world economic crisis, the advent of fascism in 1930s, the aftermath of the World War II, the Cold War confrontation, the crisis of the welfare state, the collapse of the Soviet system, and the establishment of globalization. According to Kendall (1978) and Healy (2001, 2008), the history of the IASSW can be divided into certain stages: (1) the founding (1926–1928); (2) the early years: progress and the growing threat of depression and aggression; (3) the prewar years; (4) World War II: a crisis in leadership and the destruction of war; (5) the postwar years: recovery and opportunity; (6) the 1950s and 1960s: a time of expansion; (7) 1970s: first permanent secretariat and large scale project; (8) the 1980s: international politics and the IASSW; (9) the international politics and the IASSW – 1980s; (10) the Secretariat dissolved – 1990s; and (11) entering the twenty-first century. However, these stages might be grouped into longer periods for review of the key issues in the IASSW institutional history.

1920–1930s: The Formative Phase

The founding of the IASSW has its roots in the organizing committee established in 1926 to plan the First International Conference of Social Work in Paris (Healy, 2008). It initially comprised of 51 schools, mostly in Europe, and was known as the International Committee.

An international conference on social work education organized by Dr Rene Sand in Paris in 1928 and its section on social work education chaired by Dr Alice Salomon of Germany gave birth to the IASSW, as well as to the ICSW and to the predecessor organization of the IFSW. These major international social work organizations provided leadership in connecting international agencies and international development organizations to social work worldwide.

At the time of the First International Conference, 111 schools of social work had been identified as potential members. Of these, 46 from 10 countries agreed to join as founding members (Kendall, 1978). The minutes of this first meeting also indicate that there were representatives among the delegates from India, the Philippines, Africa, and Latin America. This was a significant indication of IASSW's commitment to be international, and impressive for its time.

The first statement of purpose showed the direction for the setting up of international exchange across schools of social work and was outlined by the delegates of the training session

at the first international conference. Alice Salomon was elected as President of the IASSW.

Religious affiliation was a source of early conflict for the organization and limited success in enrolling schools. Kendall (1978) summarizes correspondence from Salomon noting that the schools affiliated with the Catholic International Union for Social Service viewed the International Committee as too neutral on religion. On the other side of the issue, leaders from the United States indicated that they opposed any mention of religion in the organization's constitution. In her report to the International Committee meeting held in Frankfurt in 1932, Elizabeth Macadam speculated that other schools had not affiliated with the committee for financial reasons (Kniephoff-Knebel and Seibel, 2008).

Alice Salomon came from a Jewish family and was known for her commitments to pacifism, women's rights, and international connections (Healy, 2008). After 1933 the German Welfare Schools tried to dismiss from her position as president. Salomon reluctantly agreed in order to save the organization; however, the International Committee refused to follow these demands and reinstated her as President. Kuhlmann (2001) observed that it was evidence of the antiracist attitude in the IASSW that they refused to do so.

Salomon was exiled from Germany in 1937. She settled in the United States and while she retained the formal title of head of the International Committee, she was unable to provide strong leadership.

Between 1928 and 1936, exchanges between schools, comparative studies to examine similarities and differences in social work education in member countries, and collection of information on social work education were the major activities of the international committee (Kniephoff-Knebel and Seibel, 2008). The committee participated in the second World Conference of Social Work in Frankfurt in 1932 and the Third World Conference in London in 1936. The fourth conference planned for 1940 was canceled due to the Second World War.

It is notable that efforts to establish linkages with intergovernmental organizations began almost immediately after its formation. The committee established working relationships with the International Labor Organization (ILO) and with the Commission on Social Questions of the League of Nations. A particularly important achievement was the creation of a center of documentation of schools of social work in 1929 in collaboration with the ILO, the precursor to several future world surveys and censuses of social work education (Kendall, 1978). Kendall's work at this time also led to IASSW's involvement in the devising of the Universal Declaration of Human Rights and the granting of Consultative Status at the UN for IASSW in 1947.

1940–1950s: Crises and Restoration

Membership grew under Salomon's leadership, and by 1939, included 75 schools in 18 countries. During this same period, however, all the German schools withdrew from membership in protest over Salomon herself.

During the 1940s, after World War II started, international meetings and even international communications were almost impossible. Elinor Black of the United Kingdom functioned as a secretary during the war years and attempted to keep in touch with social work education to the extent possible (Healy, 2008).

According to Kendall (1978), 1945–1954 were the Restoration Years for the International Committee of Schools of Social Work. As the organization began to regroup, it immediately pursued affiliation with the newly launched UN, and in 1947 it was granted class B consultative status with the Economic and Social Council as an NGO, underscoring the importance of the mission of representing social work education in global deliberations.

By 1956, the organization had changed its name to the current one, the International Association of Schools of Social Work. The Board of Directors elected in 1956 included members from Australia, Guatemala, Japan, and India. As schools of social work developed in the newly independent countries in Asia and Africa, membership grew. In 1954, there were 217 member schools in 27 countries.

With the International Council on Social Welfare (ICSW), the IASSW launched the journal *International Social Work*. The first issue was published in 1958. IFSW joined the team of sponsors in mid-1959 (Healy, 2008).

1960–1990s: Years of Expansion

During the 1960s, the organization became a more truly international one in terms of membership and leadership. In 1968, IASSW membership included 350 schools in 46 countries (Kendall, 1978). The world conferences, too, moved to new locations. In 1962, the Congress was held in Brazil, the first IASSW Congress in Latin America. This reflected the new process of the support of social work educators in different countries. Drucker (2005: p. 6) stressed that for the nearly 30 years of the IASSW existence "International was very much American and European. It was not until the early 1960s that Western-educated social workers emerged to help create social work schools in the developing and newly independent countries."

By the late 1960s, IASSW Vice-Presidents were elected from the Philippines, Ethiopia, Panama, and Finland, further solidifying the association's global identity (Healy, 2008). The expansion in leadership of the IASSW was in step with an incredible spreading out of its educational services. Social work and social work education expanded fairly rapidly to the newly independent countries in Asia and Africa.

Another highlight of the 1970s was that the IASSW Congress was held in Africa for the first time. The 1974 conference took place in Nairobi, Kenya, and drew a larger than the usual number of delegates from Africa.

In the early 1970s, IASSW secured grant funding to carry out a major project on education for the social dimensions of family planning. The grant funded a full-time secretary-general and a secretariat. The project involved curriculum development and training seminars for faculty in 20 countries across Africa, Asia, Caribbean, and Latin America.

In 1980s, IASSW faced a serious problem of 'racism' against schools of social work in South Africa. The Nordic schools withdrew their membership as a reaction to the apartheid in South Africa. Later, after apartheid, they returned with the end of apartheid in large numbers (Healy, 2008).

Since 1983, the social work profession has sponsored Social Work Day at the UN. Initially hosted by the IFSW, IASSW became a cosponsor in 1989. While about 200 social workers participated in the early years, today the conference attracts as many as a 1000 social workers to the UN (Wetzel, 2012). The mission of Social Work Day at the UN is twofold: (1) to educate social workers and social work educators about what the UN is doing and how social work can participate, and (2) to educate the UN – its agencies, governments and missions – about the relevance of social work in achieving its shared goals. The two entities have similar human rights and social justice ethos and objectives (Nadkarni, 2013).

In 1984, to commemorate Eileen Younghusband (UK) who was an IASSW President from 1961 to 1968, the biennial Eileen Younghusband Memorial Lectures was inaugurated. A current social work educator is invited to speak at the IASSW Congress on a topic of relevance to international social work. The most recent person nominated for this honor was Professor Walter Lorenz from Italy, an established social work author and former President of the European Center for Community Education, who gave this lecture during the 2012 World Social Work Congress in Stockholm, Sweden.

In 1992, the Katherine A. Kendall (now Memorial) Award was introduced to honor the late IASSW Honorary President Dr Katherine A. Kendall (USA). The most recent recipient of this award was Professor Lena Dominelli from UK (2012).

In 1990s, IASSW faced a financial crisis due to the withdrawal of the subsidy and funds by the government of Austria to run the Vienna office as the costs continued to escalate (Healy, 2008). As IASSW was not able to keep salaried persons, it became dependent on the leadership of its Executive Committee, Board and volunteers to run the Association, emerging successfully from the crisis in 1998 (Dominelli, 2004).

2000–2010s: Internationalization of Social Work and Education

The challenges to the profession in the twenty-first century are enormous, including the impact of globalization on microlevel practice; the frequency of natural disasters; increasing armed conflicts throughout the globe; rising numbers of children and older people in poverty; social injustice; the sex trade in women and children; and organized crime. All pose fundamental issues for international organizations embedded in civil society, including IASSW, to address (Tasse, 2008). Social work education has embraced a global perspective on many fronts: curriculum transformation, study abroad, student and faculty exchange, and collaborative overseas research, engagement with the latest global issues including climate change, among others.

As the twenty-first century proceeds, the reality of global interdependency is widely appreciated (Healy, 2001). IASSW partnered with the IFSW on development and approval of four important policy statements for the profession of social work in the era of globalization: the International Definition of Social Work; the Ethical Principles; the *Global Standards for Social Work Education and Training*; and the Global Agenda for Social Work and Social Development.

The IASSW and the IFSW had worked together to formulate a Definition Statement (see http://www.iassw-aiets.org/international-definition-of-social-work) officially approved by both at their respective General Assemblies in 2000 and by both organizations jointly in 2001 in Copenhagen. It runs as follows: "The social work profession promotes social change, problem solving in human relationships and the empowerment and liberation of people to enhance well-being. Utilising theories of human behavior and social systems, social work intervenes at the points where people interact with their environments. Principles of human rights and social justice are fundamental to social work" (Hare, 2004: 418).

The new international definition of the social work profession replaced the IFSW definition adopted in 1982. It was based on the understanding that social work in the twenty-first century is dynamic and evolving, and therefore no definition should be regarded as exhaustive. Lorenz (2001) considered the ambiguities, tensions and contradictions of the social work profession, which have to be constantly negotiated and renegotiated, rather than resolved, to constitute its success and challenge. The definition and comments to it provide the parameters of broad ethical principles that cannot be refuted on an ideological level.

In 2004, the IASSW and the IFSW formally approved at the General Meetings in Adelaide (Australia) the document *Ethics in Social Work, Statement of Principles*. This document cites the definition and lists seven human rights treaties as "particularly relevant to social work practice and action." The purpose of the documents of IASSW and IFSW on ethics is "to promote ethical debate and reflection in the member organizations, among the providers of social work in member countries, as well as in the schools of social work and among social work students" (Banks et al., 2008).

A major initiative in the early twenty-first century was the development and publication of "Global Standards for Social Work Education and Training." This document was presented to the General Meetings of the IASSW and the IFSW at a joint Congress in Adelaide (October 2004) and was accepted by both organizations with implications for the transferability and portability of qualifications. This document consists of nine sets of standards: school's core purpose or mission statement; program objectives and outcomes; program curricula including fieldwork; core curricula; professional staff; student social workers; structure, administration, governance and resources; cultural diversity; and social work values and ethics (Sewpaul and Jones, 2004).

These standards are the first worldwide guidelines for enhancing social work education. At the same time neither the IASSW nor the IFSW are playing any monitoring, control, or accreditation function at the level of the any given school.

In 2012, the *Global Agenda for Social Work and Social Development: Commitment to Action* was released. This document was designed by the IASSW, the IFSW, and the ICSW to strengthen the profile of social work and to enable social workers to make a stronger contribution to policy development. The paradigm of the Global Agenda for Social Work asserts that the context in which social work is practiced is deeply influenced by globalization, particularly the political form of globalization which has seen a spread of neoliberal policies through the introduction of market forces (Jones and Truell, 2012). The Global Agenda commits the three organizations to addressing the root causes of oppression and inequality. They are dedicated to

leading a movement that will create a more socially just and equitable world.

Conclusions

IASSW's support for academic scholarship and research have borne fruit in a number of areas, including in the establishment of schools of social work where none existed before, engagement in current topical global issues, e.g., climate change, through advocacy work; and supporting the development of newly emerging fields in the profession.

International Business

Mauro F Guillén, The Wharton School of the University of Pennsylvania, Philadelphia, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

International business has to do with trade and direct investment across borders. Research in this area has been undertaken from economic, managerial, and sociopolitical perspectives. Globalization has introduced a new dynamic into the field, as has the rise of the emerging economies and of the emerging market multinationals.

The term 'international business' refers to economic activities that take place across the boundaries of nation-states. The most important of these are trade and foreign investment. Merchandise *trade* has grown 12-fold since the end of World War II, and trade in services has increased even faster since the early 1980s. Foreign *direct* investment (as opposed to portfolio investment not seeking the managerial control of the foreign asset) has grown at a rate twice as fast as that of trade. *Foreign direct investment* gives rise to multinational enterprises, i.e., firms with operations in more than one country (*see* Multinational Corporations). There are nearly 104 000 of these enterprises in the world today, which collectively control about 882 000 affiliates. They account for one-third of world merchandise trade and for the vast majority of trade in technology (UNCTD, 2011). While theories of international trade were first put forward during the sixteenth century and have largely remained the province of economics, the study of foreign direct investment and the multinational enterprise started only after World War II and has been approached from a variety of social and behavioral perspectives. The three most important ones – economic, managerial, and sociopolitical – are covered here (Table 1).

Modern economic thinking about foreign direct investment and the multinational enterprise properly starts with Stephen Hymer's (1960) MIT thesis, posthumously published in 1976. The key insight was to see foreign direct investment not as a capital movement but as the decision of a firm to produce some goods or service in a foreign location. Hymer noted that foreign direct investors did not seem to go abroad in search for higher interest rates – as the theory of investment would predict. Rather, he argued that "control of the foreign enterprise is desired in order to remove competition between that foreign enterprise and enterprises in other countries" (Hymer, 1976: p. 25). Thus, Hymer was the first to observe the *oligopolistic* behavior of the firm that engages in foreign direct investment. In other words, the multinational was seen as an anomaly that could only be explained by reference to imperfections in the markets for production factors and goods, economies of scale, and/or government intervention. The most complete rendering of the oligopolistic thesis is that of Knickerbocker (1973). He observed that firms in a loose-knit oligopoly in the home country match each other's investments in foreign locations following a pattern of action–reaction or move–countermove out of fear that not keeping up with rivals might erode their profitability and competitive position or endanger their sources of supply.

Hymer was also the first scholar to note that "the control [of a foreign enterprise] is desired in order to appropriate fully the returns on certain skills and abilities" (1976: p. 25), especially those having to do with product and process innovation.

Table 1 Three perspectives on international business and the multinational enterprise (MNE)

	Economic	*Managerial*	*Sociopolitical*
Name of the literature(s)	IB (International Business)	IM (International Management)	Development Studies and International Relations
Research community	AIB (Academy of International Business) and AEA (American Economic Association)	AIB and AoM (Academy of Management)	ASA (American Sociological Association) and APSA (American Political Science Association)
Research questions	Why do firms go abroad? How do they go abroad? What are the welfare implications?	Why and how do firms go abroad? How are MNEs organized?	What role do MNEs play in economic and political developments, and in international relations?
Assumptions and answers	Rationality; constrained maximization; calculation of trade-offs	Capability-based strategies; organizational structure follows strategy	Power and interest drive processes and outcomes
Ways of doing research	Deductive reasoning; formal modeling; large samples	Conceptual framing; grounded theory; case studies and large samples	Mostly inductive; grounded theory; case studies; comparative-historical method
Key scholars	Hymer (1976); Caves (1996); Knickerbocker (1973); Vernon (1966); Buckley and Casson (1976); Dunning (1979); Kogut (1983)	Perlmutter (1969); Stopford and Wells (1972); Wells (1983); Prahalad and Doz (1987); Bartlett and Ghoshal (1989)	Vernon (1971); Moran (1974); Kobrin (1982); Gilpin (1987); Haggard (1990)

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73003-0

Vernon (1966) further argued that patterns of trade and foreign investment had to do with the so-called 'product cycle' and not so much with comparative advantage. Vernon saw entrepreneurs and managers as relatively myopic, i.e., most knowledgeable about, and responsive to, conditions in the home market. The features of new products reflected characteristics of the home market and affected the pattern of foreign expansion of the firm. Vernon proposed that firms would only pursue foreign market opportunities after the home market became saturated. Foreign markets relatively similar to the home market in terms of purchasing power and tastes would be entered first, and exports would probably be the preferred mode of entry. Licensing or foreign production would come later in response to host country protectionism and/or rising production costs in the home country. Vernon's insights were further developed by Swedish scholars (Johanson and Vahlne, 1977).

The economic approach to the multinational enterprise acquired a high degree of internal consistency after scholars started to draw from the insights of transaction cost economics (*see* Transaction Costs and Property Rights), which has become the backbone of the widely accepted view among economists that multi-nationals are an efficient governance response to certain market failures (Buckley and Casson, 1976; Dunning, 1979; Caves, 1996). The multinational enterprise is expected to exist if two conditions are met. First, the necessary condition is that there be differences in the productivity and cost of production factors by location (in the case of vertical expansion by multinationals) or significant transportation costs, trade protectionism, adverse changes in exchange rates, and/or needs to customize products to local demand (in the case of horizontal expansion). Transaction cost theory, however, warns that a second, sufficient condition must be met in order to guarantee that foreign production will be managerially controlled by a multinational firm: market failure due to asset specificity or uncertainty (vertical expansion) or the possession of intangible assets such as patents, brands, and other proprietary skills that cannot be protected in a contractual, arm's length fashion (horizontal expansion). A final, distinctive contribution to the economic approach was made by Kogut (1983), who proposed to see the multinational enterprise as a flexible network in which resources are arbitraged across borders, a view that revisited Vernon's insight that multi-nationals approach foreign investment decisions as a sequential process. A significant body of empirical evidence exists corroborating the major tenets of the economic approach (Caves, 1996).

While the economic approach has focused on the questions of why and how firms go abroad, the managerial approach has contributed an understanding of how multinationals are organized and managed. This second approach relies on typological conceptual frameworks and inductive reasoning rather than formal modeling. In addition, theoretical development frequently results from case studies, although testing of the main propositions has also been undertaken with large samples, as in the economic approach. Perhaps the first noteworthy typology of the multinational enterprise in the managerial literature was proposed by Perlmutter (1969), who distinguished among three types of multinational 'mindsets.' Ethnocentric multinationals are the ones assumed by Vernon's (1966) produce-cycle approach. They have simple but inflexible organizational structures. Polycentric multinationals, by contrast, adapt to local circumstances but have difficulty in coordinating. Finally, geocentric multinationals are costly but very good at gathering and integrating information from various locations. Drawing on a rich data set on US multinationals assembled under the coordination of Raymond Vernon, Stopford and Wells (1972) presented the first comprehensive treatment of the various factors at the firm, industry, and country levels affecting the choice of organizational structure and degree of ownership over the foreign subsidiaries of the multinational firm. Wells (1983) extended this kind of analysis to the case of 'Third World' multinationals, i.e., firms from developing countries that engaged in foreign direct investment.

The early insights by Perlmutter, and Stopford and Wells were further developed in their respective dissertations by Prahalad and Doz as the 'integration-responsiveness' framework (Prahalad and Doz, 1987). Multinationals are seen as organizations responding to environmental pressures for global integration (so as to reduce costs through economies of scale and scope) and to pressures for local responsiveness (so as to adapt to local tastes, institutions, or regulations). Following the strategy-structure paradigm in organizational theory, they identify different organizational structures and managerial processes that allow multinationals to operate under different configurations of global integration and local responsiveness. Bartlett and Ghoshal (1989) proposed an influential analytical framework also emphasizing the tension between global and local opportunities or demands that every multinational has to deal with. Although still in its infancy, a neoinstitutional approach to the multinational enterprise as a firm exposed to isomorphic pulls from both the home and the host country is also emphasizing the organizational problems associated with multinationality (Westney, 1993; see Institutional Theory).

A third perspective on international business has built on the insights of both the economic and managerial approaches to the study of the political and social context of multinational activity. Vernon (1971) was the first to explicitly argue that the spread of multinational corporations creates 'destructive political tensions,' and that there is a 'need to reestablish balance' between political and economic institutions.

Political scientists have looked at the impact of multinationals on international relations. For example, neorealist scholar Robert Gilpin (1987) argues that changes in the international location of activities due to foreign direct investment have reinforced the importance of domestic policies, as countries engaged in regionalization, sectoral protectionism, and mercantilistic competition during the 1980s so as to cope with globalizing trends. Other political scientists have been concerned with the relative bargaining positions of host governments and multinationals. In a classic book, Moran (1974) analyzes Chilean efforts to seize control over its vast copper industry, finding that nominal ownership and control does not guarantee success in a worldwide oligopoly. Haggard (1990) summarizes the bargaining power literature writing that the host government is relatively powerful vis-à-vis multinationals making huge fixed investments (e.g., in extractive industries), relatively

weak when dealing with export-oriented firms looking for cheap labor, and weakest when multinationals are attracted by import-substitution policies that create a political base of support among local suppliers, distributors, employees, and joint-venture partners. Kobrin (1982) offers a different, yet complementary, approach to the politics of multinational activity by examining how multinationals evaluate political risk and try to protect themselves against it.

Sociologists have also examined the effects of international business activity on economic growth and inequality in the world. One major controversy in the literature is whether foreign investment retards long-term economic growth and exacerbates income inequality in the host country or not. Capital dependency theorists have long argued in the affirmative using cross-national empirical evidence (Dixon and Boswell, 1996), while other sociologists pointed out that the data do not support such claims (Firebaugh, 1996). This protracted debate – now three decades old – does not take into account the fact that the effect of foreign investment on host-country growth and income inequality is mediated by the economic development strategy of the host government. Countries allow more or less foreign investment depending on a number of ideological, political, and economic considerations, and the effects of multinational activity differ widely between import-substitution and export-oriented contexts (Haggard, 1990). While it is easy to point to examples of the harmful effects of multinationals, and even of their outright wrongdoing, the social-science literature has been slow to recognize that they have played a largely constructive role in many countries – e.g., Singapore, Malaysia, Puerto Rico, Ireland, Portugal, and Spain – in which even organized labor and the left have welcomed them.

Over the last 20 years, the expansion of international business activity has acquired a new, qualitatively different outlook. *Globalization* at the turn of the twenty-first century is different from the internationalization of the world economy during the nineteenth century through increasing cross-border flows of trade and investment. The 'global' economy of the late twentieth century and into the twenty-first century is driven by the increasing scale of technology, the surge in cross-border collaboration between firms along the value-added chain, and the cross-border integration of information flows. While the conventional wisdom is that late-twentieth-century globalization undermines the nation-state and compels firms to converge toward 'universal best practices,' sociologists and political scientists document that governments exercise a great deal of choice in the global economy and firms continue to adopt organizational structures and patterns of behavior that are related to the institutional conditions in their home countries (Orrù et al., 1997). Thus, globalization is far from being a monolithic, uniform, and inexorable trend. Rather, it is a fragmented, contradictory, and heterogeneous process of change. More empirical and theoretical research is needed to describe the causes of globalization – including those having to do with international business activity – and to understand its effects on political, economic, and social outcomes in various parts of the world.

Perhaps the most important new development in the world of international business is the rise of the so-called emerging market multinationals, companies from emerging and developing economies that have made important investments abroad. In 2011, 29% of the 104 000 multinational firms in the world originate from emerging and developing countries, up from 21% in the year 2000. They account for about 15% of global stocks of cumulative foreign direct investment, and between 2006 and 2010 they were responsible for 41% of new foreign direct investment flows. What's more important, 120 emerging market multinationals are among the top 1000 corporate spenders on research and development, indicating that these firms are competitive in terms of low labor cost. In fact, many of them have come to dominate entire industries, like Bimbo of Mexico (bread), Embraer of Brazil (regional jets), BYD of China (rechargeable batteries), or Tata Communications of India (wholesale voice traffic). The emerging market multinationals already account for 25% of the Fortune Global 500 ranking of the largest companies in the world in terms of revenue (Guillén and Ontiveros, 2012).

The rise of the emerging market multinationals poses interesting questions about the nature and future evolution of international competition (Guillén and García-Canal, 2009). They have expanded around the world much faster on average than the multinational corporations from Europe or the United States, based on less obvious and relatively incipient competitive advantages. Many of them lacked a strong brand image before expanding abroad. They are also more likely to leverage political skills, frequently developed in the home market. They tend to use alliances, joint ventures, and mergers and acquisitions to a much greater extent than wholly owned subsidiaries and greenfield investments. Finally, most of the emerging market multinationals are companies owned and controlled by the state or families. These peculiar patterns of ownership and control raise numerous issues and have been the source of heated controversies given that governments in Europe and the United States have so far been willing to prevent some emerging market multinationals from controlling strategic assets in their economies.

As the twenty-first century roars on, the world of international business continues to undergo a profound transformation driven by the impact of information technology, social media, the growth of the emerging economies, and the fallout from the 2008 financial crisis. Research is likely to focus on the characteristics, relationships, and impact of these new actors and types of firms, and on the implications of their proliferation and growth for global competition.

International Business: Geographic Aspects

Sharmistha Bagchi-Sen and Torsten Schunder, State University of New York – Buffalo, Buffalo, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article provides an overview of the evolution of understanding multinational enterprise (MNE) activities. Between World War II and the late 1990s, there was a major focus on understanding foreign direct investment (FDI) by MNEs. In the past 20 years, recognition of commodity chains, value chains, and production networks at the global scale has prompted researchers to develop new frameworks to incorporate the complexity of MNE operations spanning many countries and industries. This article explicitly recognizes geography as a key factor (e.g., location determinants, local impact, role of policy).

Introduction

A major aspect of international business is the worldwide spread of MNEs, also known as multinational corporations (MNCs) and transnational corporations (TNCs), whose operations are organized across borders. The United States, Europe, and Japan still dominate as the main sources of MNEs. However, South Korea, Taiwan, Singapore, China (including Hong Kong), India, Brazil, and Russia are some of the countries with emerging MNEs in the twenty-first century. Foreign direct investment, an active investment in a foreign country made by either acquiring a partner in the host country or establishing a new operation, is the main mode of entry by MNEs into other countries. The theoretical foundation for studying FDI includes theories focusing on market imperfections, that is, the possession of certain advantages (e.g., knowhow, finance) by a few firms, which give them competitive advantage over others in an international market.

Historically, asset exploitation (e.g., direct sales of goods and services) has been the focus of MNEs. More recently, asset augmentation has become an integral part, that is, MNEs are now interested in gathering market intelligence to tailor their products for particular niche markets. Furthermore, firms have global networks of suppliers and distributors, as well as cooperative arrangements, like strategic alliances and joint ventures, to pool resources and reduce risks, to manage worldwide research and development (R&D), production, and sales. This article reviews the evolution of research on FDI, with a focus on the importance of the geographic location of nations – as facilitators (e.g., availability of cheap labor in the host country); as negotiators (e.g., the designation of export processing zones by the host country), and as recipients of the impact of FDI (e.g., technology transfer).

Explanations of Foreign Direct Investment

Before Hymer's (1976) groundbreaking dissertation in 1960, scholars assumed that firms invested internationally to profit from real interest rate differentials; FDI was seen as a special kind of portfolio investment with additional control functions (Hennart, 2010). Hymer challenged these assumptions by hypothesizing that firms undertake direct foreign investment to further their competitive advantages at home and abroad. By internalizing pecuniary externalities caused by market imperfections (e.g., barriers of entry, oligopolistic industry structure, government interventions), firms could achieve monopolistic profits in foreign markets based on an internal competitive advantage (Buckley and Casson, 1976; Hennart, 2010; Caves, 2007; Kedron and Bagchi-Sen, 2012).

Hymer's (1976) approach saw the motivation for FDI in the effort to preserve a position within an oligopolistic system by preventing the emergence of foreign competition in the context of reduced trade barriers; this view sees MNEs as exploitative, with governments expected to regulate their activities so that local industry and entrepreneurs are not squeezed out of the market (Hennart, 2010). Hymer's work is the foundation for the internalization theory, which explains the incorporation of processes in an organization allowing for high degrees of control and remains an important part in today's approaches to explaining FDI (Dunning, 2003). Internalization theory further explains why firms pursue FDI in lieu of exports or licensing; internalizing transaction costs in the international market to manage uncertainties is a major motivation in FDI decisions.

Dunning (1977) was the first to introduce location as an important determinant of FDI in his eclectic paradigm. This paradigm addresses the why, how, and where of FDI activities (Dunning, 2009a,b): a firm will undertake FDI if a combination of firm-specific advantages – ownership advantage (O), location-specific advantages of the host country (L), and internalization (I) of operations – create an overall benefit for the company. A company enters a foreign market via FDI if it possesses a specific competitive advantage (e.g., technology, skills), if the internalization of operations provides benefits, and if the host country provides a locational advantage (e.g., lower labor cost, resources). In the absence of internalization or locational advantages, a company would opt to export its goods/services; and licensing would be the preferred mode of entry if a company has only one particular type of ownership-specific advantage (e.g., patents) (Dunning, 1977).

FDI enables a company to maintain and protect its initial competitive advantage over competitors in a host country by internalizing operations, establishing hierarchies (e.g., vertical integration), and enhancing the security of transactions while controlling the diffusion of knowledge. The ability to internalize and thereby obtain better control of

market factors – e.g., suppliers or retailers – is another advantage. But internal markets are suitable only for specific industries or company structures whereas others fare better with external markets (e.g., outsourcing), which can eliminate inefficient parts of a production process (Hennart, 2010; Buckley and Ghauri, 2004; Buckley, 2009).

The ownership-location-internalization (OLI) paradigm has incorporated new developments as Dunning (2009b) elaborated. Generally, in the 1970 and 1980s, firms made locational choices to focus on asset exploitation (e.g., access to markets such as foreign direct investment in the United States). In recent years, asset augmentation (e.g., access to innovative ideas or codified knowledge such as FDI in Europe by Chinese and Indian firms) has been an important aspect of FDI, which includes investments by emerging market MNEs (EMMNEs) in developed economies (Ramamurti, 2010). Previously, locational determinants did not explicitly include external economies or the importance of clusters (e.g., core regions, global cities), which provide learning networks, proximity to specialized labor, and other intangible benefits not addressed by transaction cost theory. Also the importance of institutions at various geographic scales and new forms of international cooperation, ranging from a diversity of new equity-based cooperation to nonequity-based cooperation, have received increasing attention within the last decade.

In the context of emerging forms of cooperation in international business, other organizational frameworks like the global commodity chain (GCC), global value chain (GVC), and global production network (GPN) emerged. The GCC is based on networks related to a specific commodity linking households, enterprises, and states and is strongly characterized by buyer–supplier dependencies (Buckley and Ghauri, 2004). A GVC includes all value-added activities related to a product beginning with R&D, production, marketing, and distribution. Gereffi et al. (2005) identify three modes of governance (modular, relational, captive) between market relations and hierarchies, which differ in the degree of power exerted by a lead firm on its suppliers/customers without direct ownership (**Figure 1**). The GPN framework addresses the multiactor and multiscalar characteristics of transnational production systems based on power, value, and embeddedness; the GPN concept is related to the GVC approach (Coe et al., 2008).

Three main modes of governance operate within these frameworks: (1) traditional FDI is used to organize and coordinate crucial functions; (2) arm's-length transactions are buyer–seller relationships subject to market forces; and (3) nonequity modes (NEMs) are characterized by various degrees of buyer–seller dependencies (UNCTAD, 2013). Though other forms of governance exist, FDI remains an important tool to reduce uncertainty by internalizing crucial aspects of the international business process.

Because MNEs are main actors in international business, their strategic orientation and decisions are essential. Their modes of governance and internalization decisions aim to reduce economic risk by increasing reliability and control over the production process (Yeung, 1999; Guillén and García-Canal, 2009). *Vertical integration* strategies aim to internalize backward- or forward-oriented parts of the value chains, which can include resource procurement or the securing of distribution channels. *Horizontal integration* establishes operations in a new market while maintaining production in other

Figure 1 Five global value chain governance types. Reproduced from Gereffi, G., Humphrey, J., Sturgeon, T., 2005. Governance of global value chains. Review of International Political Economy 12, 78–104.

places. *Diversification strategies* aim to increase the product portfolio and thereby reduce a company's dependence on just one product group. *Risk reduction behavior* determines how a company enters a market (Guillén and García-Canal, 2009); for example, Chinese MNEs use joint ventures to gather market intelligence before committing to a large FDI (Yeung, 1999). Related literature discusses strategies of first movers, imitators, latecomers, and others in the international market.

Locational Determinants of Global Value Chains and Foreign Direct Investment

The recent World Investment Report (UNCTAD, 2013) provides an extensive discussion of global value chains and their locational determinants, a discussion that is also valid for understanding FDI within the GVC. In general, during all stages of the value chain, important factors are political, economic, and social stability; a sufficient institutional framework (e.g., policies, accounting and finance regulations, intellectual property rights); labor force suitability; geographic access to markets or the next value chain activity; transportation and logistics infrastructure; and the presence of local firms. All these factors lead FDI in nonextractive sectors to locate in urban or core regions.

If the globalization of R&D activities is considered, important locational factors are the national innovation system, the supply of educated labor force in science and technology, and the presence of institutions facilitating research and the translation of research for commercialization. Also important is the policy environment, including R&D policies, intellectual property laws as well as general laws and regulations governing contract research and licensing, the presence of science and technology parks, and investment incentives. Other aspects important for R&D are local consumer preference, local design capabilities, policies and institutional support to learn from local consumers (e.g., the presence of nongovernmental organizations as mediators between the multinational and the market). Relevant factors for the production aspect of a value chain are cost and quality of input materials and access to intermediate goods. Locational determinants for this stage include resources for processing, the availability of utilities, low-cost and trained labor, as well as sufficient transportation and communication infrastructure. The distribution stage requires access to a network of distribution and logistics companies.

Clearly, location determinants range from national to regional/local characteristics. With reference to operational aspects, Buckley and Ghauri (2004) note that MNE strategies are often focused on balancing the opposing pressures of global and local, that is, accommodating geographic variations in every aspect affecting business within a globalized world. Global operations provide cost advantages based on the potential of realizing economies of scale and increasing efficiency, whereas the local level requires specialization, adaptation, and product differentiation, which in turn provides a company with niche markets and high profit margins.

New locational determinants have gained importance in the context of emerging market economies, which have large markets, with large shares of low-income consumers who are highly price sensitive. People living in environments of scarcity improvise with available resources to maximize usage value, which can lead to surprisingly efficient results and an overall culture of creative makeshift innovation (e.g., 'jugaad' or frugal innovation in the Indian context). Such frugal innovation or grassroots innovation has the potential to increase overall resource efficiency and open new market opportunities at the bottom (or base) of the pyramid (BoP) if companies are able to access knowledge of the BoP and adapt to the local context (Bound and Thornton, 2012). Also within its own network, a company might be able to create competitive advantage if it is able to incorporate suppliers, customers, and global clusters of businesses cooperating with each other (Mathews, 2006). Access to such networks is critical for host country companies that want to become part of a global value chain. Furthermore, some companies originating in an emerging country have accumulated enough revenue from their own markets to venture into FDI for asset augmentation (e.g., Indian pharmaceuticals in Europe).

While manufacturing has been the traditional focus of FDI studies, more recently the R&D activities of specific industries and sector-specific analysis (e.g., information technology and other services) have attracted scholarly attention (Coughlin and Segev, 2000; Coe and Hess, 2005; Dunning and Lundan, 2009). With the increasing division of labor and new modes of organizing the labor process that enable companies to optimize the location of specific steps in the value chain (Glasmeier, 1986; Buckley and Ghauri, 2004; UNCTAD, 2013), the locational determinants of international business activities (e.g., availability of cheap educated labor) have become highly context-specific. This context specificity is illustrated in numerous studies of FDI in particular destinations such as FDI in the United States, FDI in the UK, or FDI in China. For example, the volume of FDI in the United States attracted research over the past 30 years to understand state-level patterns of FDI within the United States (Bagchi-Sen and Wheeler, 1989). In the 1980s and 1990s, Japanese FDI was a popular choice of inquiry, with focus on the variety of destinations of such investments in the automobile industry and the creation of auto alley in the United States (Poon et al., 2013). Now, the volume of FDI in emerging economies like China and India has spurred research on certain sectors and regions, such as FDI in information technology in Bangalore, India.

By using a taxonomy of market-seeking, resource-seeking, efficiency-seeking, and strategic asset-seeking FDI, work on locational determinants has mostly obscured the role of geography and place. Empirical analyses that have included geographical factors have shown how locational determinants affect business decisions at various scales ranging from the local to the national level and even global regions (Bagchi-Sen and Wheeler, 1989; Coughlin and Segev, 2000; Dunning, 2009a). Researchers have examined variations in the location determinants of FDI based on mode of entry (e.g., acquisition or greenfield), industry sector, value chain operation (e.g., type of production), structure of the multinational enterprise (e.g., centralized or decentralized governance), strategies of the MNE, and environmental factors – e.g., the 'policy environment,' such as the development of export processing zones, the level of

corruption, IP regime (see Dicken, 2011). Now, the complexity of global networks necessitates examination of specific aspects of value chain creation and their impact and a burgeoning field of study now focuses on the impact of GVC and FDI on local economies, with a focus on development outcomes (Coe et al., 2008; Dicken, 2011; UNCTAD, 2013)

Emerging Market Multinational Enterprises

Japanese FDI as well as the more recent EMMNEs from the BRIC (Brazil, Russia, India, and China) countries have required new theorization. Historically, Japan was not well integrated within the global economy until government reforms encouraged companies to invest abroad; this shift led to Japan's position alongside the United States and Europe in total volume of outward FDI, which exceeded 120 billion US dollars in 2012 and had a growth rate of 14% in 2011–2012. Japan's inward FDI was less than two billion US dollars in 2012, whereas FDI for the United States and Europe is more balanced between inward and outward flows (UNCTAD, 2013; Branstetter, 2006). Major destinations of Japanese FDI are developed countries like the United States, where Japan's goals are asset exploitation and augmentation. East and Southeast Asia, which receive a considerable amount of FDI from Japan, provide locational advantages for Japanese FDI in manufacturing, in terms of labor cost. Japanese FDI in the United States has been able to capture technology and transfer it to the home country but has also made contributions to the knowledge base of companies within the United States (Branstetter, 2006). South Korea, Taiwan, Singapore, and formerly Hong Kong are also established regions both as sources and destinations of FDI.

Recently, China and India have made great strides in integrating into the world economy based on infrastructure development, which is essential to global competition (Ramamurti, 2010). China has been a low-cost provider of unskilled labor, whereas India has been a low-cost provider of skilled labor. Ramamurti (2010) provides a taxonomy of EMMNEs and their generic internationalization strategies as well as their country- and firm-specific advantages (**Table 1**).

The geographic context in which companies operate, as well as their specific advantages and goals, strongly determine the path to internationalization. *Companies involved in natural resources* tend to integrate vertically to secure resources and downstream markets; they also enjoy privileged access to natural resources and markets in their home country. *Local optimizers* tend to operate in low-income markets; they have strong customer connections, along with an ability to optimize products and processes for their customers. This ability results in a product portfolio suitable for market entry into other emerging markets, where they might have an ownership advantage (e.g., Chinese and Indian FDI in Africa). *Companies with low-cost but proficient project management* aim to become low-cost suppliers to traditional MNEs but try to move up the value chain by resource augmentation (e.g., Indian information technology companies). Additionally, these companies diversify their supplier structure through downward FDI. *Global consolidators* are often involved in mature industries with internationally standardized products (e.g., steel), which makes it easier for EMMNEs to engage in international markets and to compete on a similar technological level globally as traditional MNEs while often having economies of scale advantages. Global consolidators tend to acquire poorly performing companies to strengthen their global position as suppliers. *Global first-movers* are different from the previous MNEs, in that they are involved in emerging technologies and industries and have no considerable disadvantages as global latecomers. While these companies have cost advantages in their home market, they are also close to the technological frontier and are in direct competition with traditional MNEs. These companies tend to acquire technological capabilities and market access in developed markets through FDI, and they use FDI to broaden their production base. China and India are both endowed with enormous human capital resources with unique characteristics that provide inherent competitive advantages, and they have a large market size. Having a large base of low-income labor, provides EMMNEs with the ability to create resource-efficient products and to implement frugal innovation more readily than their traditional counterparts from developed countries (Bound and Thornton, 2012).

A new form of internationalization is closing the gap between MNEs and EMMNEs and it has instigated a major review of traditional FDI motives and patterns. Whereas traditionally MNEs became internationally active over a long period of time, the process is accelerated for EMMNEs. EMMNEs may not have the traditional competitive advantages (e.g., proprietary knowledge) and they use a strategy of knowledge augmentation by undertaking FDI in developed markets. A large advantage over established MNEs is that EMMNEs have high organizational adaptability and are able to operate in unstable political environments. To be able to sell globally, EMMNEs normally apply a dual expansion strategy: (1) they expand into other emerging markets (through new or greenfield investments) where they might have advantages based on their own assets (e.g., specific products) in comparison to local competitors and (2) they invest in developed countries where they augment their resources through acquisitions (e.g., access to patents and brands) (Guillén and García-Canal, 2009; Kedron and Bagchi-Sen, 2012). For example, the Indian conglomerate Tata bought Jaguar and Land Rover in the UK, and the Chinese company Geely acquired Volvo Cars. These strategic moves enabled involvement in developed markets and resource augmentation for their car manufacturing-related operations.

Impact of Foreign Direct Investment and Global Value Chains

The impact of international business activities is a critical topic both for MNEs and host countries. While the economic impact, e.g., spillovers, has received wide attention, the social impact and corporate responsibility issues are increasingly visible. Research on FDI/GVC impact is limited given the dearth of data and contradictory findings from various stakeholders. Generally, the impact of international business activities is strongly determined by their specific geographic, industrial, and organizational contexts.

Table 1 Generic internationalization strategies of EMMNEs

Generic strategy	*CSAs*	*FSAs*	*Internationalization path*	*Examples*
1. Natural-resource vertical integrator	● Natural resource endowment and/or ● Large home demand for natural resources	● Privileged access to natural resources and/or ● Privileged access to home markets	● Forward integration to downstream markets and/or ● Backward integration upstream to secure natural resources	● Gazprom, Lukoil, Norilsk, Vale, Anglogold, PTT ● Petrobras, ONGC, Indian Oil, CNOOC, Chinalco
2. Local optimizer	● Low-income consumers ● Under-developed 'hard' and 'soft' infrastructures	● Ability to optimize imported products and processes to home market ● Local-customer intimacy and local embeddedness	● Target market: Other emerging markets	● HiSense, Mahindra & Mahindra, Tata Motors, Shoprite, Marcopolo
3. Low-cost partner	● Low-cost labor ● Size of skilled labor pool, including engineers/ scientists, etc.	● Process excellence ● Project management ● Ability to operate successfully in the adverse conditions of emerging markets	● Target market: Developed countries ● Up-market FDI to move up value curve ● Down-market FDI to diversify supply locations	● Wipro, Infosys, TCS, Dr. Reddy's, WEG, Sabo
4. Global consolidator	● Large and rapidly growing home market ● Price-sensitive customers	● Production and project execution excellence ● Late-mover advantages in scale, organizational processes, technology ● Strong position in home market, with strong cash flows	● Target market: Global ● Up-market FDI to acquire poorly performing companies	● Tata Steel, Hindalco, South African Breweries, Lenovo, Wanxiang, Cemex
5. Global first-mover	● Large and rapidly growing demand in a new industry ● Low-cost country for design, engineering, and production	● Close to global frontiers of technology ● Strong position in home market, including, possibly, state support	● Target market: Global ● Up-market FDI to acquire key technologies or capabilities, and customer access ● Down-market FDI to gain market access and/or to diversify production bases	● Embraer, Huawei, Suzlon Energy, Check Point, Teva

Reproduced from Ramamurti, R., 2010. What have we learned about EMNEs. In: Ramamurti, R., Singh, J.V. (Eds.), Emerging Multinationals in Emerging Markets. Cambridge University Press, Cambridge, UK, pp. 399–426.

Among other impacts, knowledge transfer and spillovers are perceived benefits of FDI; governments partially subsidize FDI to capture these spillovers (Branstetter, 2006). Empirical evidence shows contradictions: some find evidence for a bidirectional flow of knowledge between the investing firm and the host country (e.g., Branstetter, 2006), whereas others find only a unidirectional exchange benefiting the investing MNE (see de la Potterie and Lichtenberg, 2001). Specific locational conditions, the position within a global value chain, and the corporate culture, affect the nature of spillovers. In the context of developing countries, spillovers are marginal, but a major concern with FDI is its negative impact on local competition, entrepreneurship, and forced industrial consolidation. In other words, FDI often squeezes out domestic competition and future possibilities of entrepreneurship (Oetzel and Doh, 2009). If local sourcing is encouraged, some spillovers may take place, but such spillovers are generally difficult to measure. Country-specific trade and industrial policies, the negotiating power of host governments, and MNE strategy are likely to affect the extent and quality of spillovers (UNCTAD, 2013).

A question related to FDI or the activities of MNEs is how they relate to international trade. More specifically, do they substitute trade or are they supplementing or creating trade? The traditional interpretation based on market imperfections argues that FDI is an alternative way (in lieu of exports) to serve a foreign market; that is, by producing locally to replace exports from the source country (Buckley and Casson, 1981). A host country can promote local production through import substitution policies and trade barriers to restrict inward FDI and thus promote the development of indigenous industry (e.g., India prior to market liberalization in the 1990s). Other observers argue that FDI creates trade through increased intra-industry trade and the opportunity to export adapted products to similar countries through internal corporate networks (Helpman and Krugman, 1985; UNCTAD, 2013). In the context of GVCs and GPNs, companies use intraindustry trade to optimize the location of different stages in the value creation chain in different countries. However, GVC/GPN, FDI and intraindustry trade relationships are context-specific: a country with restricted inward FDI, such as Japan, will differ from a country like Canada (Pantulu and Poon, 2003).

FDI and GVCs have the potential to capture value-added activities in their host countries. Especially for developing countries involved in or planning to be involved in GVCs, it is a challenge to participate in GVCs without adjusting social and environmental conditions, often to the detriment of both. FDI

involves transfer of capital and repatriation of profits. In this context, FDI and participation in GVCs can add value and contribute to GDP growth in the host country. If goods assembled in countries include a large percentage of imports, then value-added portions are compromised for the host nation. Job creation, income generation, conditions of work, social and environmental impacts are other areas of discussion connected not only to GVCs and FDI but also to other forms of transactions (e.g., arm's-length transactions) (UNCTAD, 2013). The potential of beneficial cooperation between MNEs and nontraditional partners (e.g., nongovernmental organizations) to achieve sustainable solutions is receiving more attention in the literature on inclusive growth and development (Oetzel and Doh, 2009). Finally, upgrading and building long-term productive capabilities are other development possibilities that might be linked to international business activities, e.g., the rise of original equipment manufacturers from Taiwan, Singapore, and now China.

Concluding Remarks

Although the global value of FDI fell to $1.35 trillion in 2012, international business remains important for the world economy (UNCTAD, 2013). In 2012, developing countries led as the top destination, absorbing 52% of total FDI, while FDI from and to developed countries fell. Deeper insights into relationships between FDI and GVC/GPN/GCC are needed. With new sources and forms of MNEs, the growing importance of knowledge intensity in goods and services, the transformation of markets, and the ever-changing political environment, international business is becoming more complex; this complexity demands multiple strategies to negotiate paths of development for the MNE and the source and host economies. Future research will focus increasingly on the role of intraindustry trade in adding value to the exporting country, and this research in turn will influence studies on strategies and structures of MNEs, which are now recognized to be deeply embedded within geographical contexts.

Abstract

Since ancient times, governments, merchants, and individuals have needed to communicate over long distances. The first public postal systems date from the seventeenth century. In the late eighteenth century, France built an optical telegraph network. Starting in the 1830s, electrical telegraphy spread in Europe and North America. The 1870s saw the laying of submarine telegraph cables connecting continents and islands. The early twentieth century saw the rapid development of international electronic communications: wireless telegraphy before World War I, radio broadcasting in the 1920s and 1930s, and global telephony and the Internet in the late twentieth century.

The first long-distance communication networks were imperial posts with messengers and relay stations. Communications between polities were carried out, sporadically, by traveling embassies. Medieval merchants, students, and clergy communicated across political boundaries. In the seventeenth century, the Thurn and Taxis family provided the first public postal service throughout Europe. Since the mid-nineteenth century, government postal services have cooperated to provide worldwide mail delivery. Napoleon built a semaphore telegraph network to link France, Spain, Italy, and Germany. Electric telegraphs crossed national borders in the 1840s. By the 1870s, telegraph lines covered Europe, North America, and India, and submarine cables connected Europe with other continents. In the early twentieth century, governments supported research into wireless telegraphy to communicate with ships and with one another. Shortwave radio, invented in the 1920s, competed with international cable and airmail services. International telephony now carries voice, fax, and data. Radio has broadcast news and entertainment since the 1920s. Today, satellites permit global television broadcasting. The Internet, still in its infancy, is already replacing paper letters between countries and is about to provide international telephone, radio, and television.

International communications includes communications between the inhabitants and between the governments of different states. Such communications have increased in speed, reliability, and volume since the beginning of civilization, until they now constitute a flood.

Ancient and Medieval Communications

Messengers were the first means of conveying information over long distances. Before the Battle of Marathon in 490 BC, Philippides, 'by profession and practice a trained runner,' ran to Sparta, 120 miles away, arriving 'on the very next day.'

Inhabitants of cities and isolated communities had no choice but to rely on messengers and travelers, but kings needed more regular communications. To keep control of their far-flung domains, the Persians established a permanent postal system with relays of horses along the Royal Road that stretched from Susa in western Iran to Ephesus on the Aegean Sea (Herodotus, 1987). The Romans created a similar network of imperial messengers and relay posts along their major roads, called *cursus publicus*. The Chinese, Inca, Mongol, and other empires established similar systems. These early imperial networks were reserved for official messages; anyone else who had a message to send would have to find a traveler going in the right direction, and hope for the best.

The Middle Ages saw the decline or disappearance of the governmental apparatus of classical times and the emergence of numerous unofficial channels of communication, some of them well organized. The Benedictine monks of Cluny entrusted pilgrims with messages to other monasteries from Spain to Poland. The merchants of the Hanseatic League carried documents and messages along with merchandise. Butchers, who traveled from place to place buying and slaughtering livestock, carried messages for people. The most organized of these nongovernmental networks was the one centered on the University of Paris, whose students came from all over Europe and carried and sent messages between Paris and their homelands. Although they were supposed to serve only the university community, in fact they commonly carried messages for the public as well. These networks were slow and unreliable, however, for they did not operate on a schedule, nor did they use relays of horses or messengers.

Postal Communications

The first postal system that established permanent relays and offered its services to the general public was founded in 1489 by Franz von Taxis, postmaster to the Holy Roman Emperor Maximilian I. The Thurn and Taxis family provided a regular postal service throughout most of Europe until 1867. With up to 20 000 messengers and relays of horses on all the main routes, their postal service was reliable and, by the standards of the day, fairly swift: from Brussels to Paris in 44 h, to Innsbruck in 6 days, and to Toledo in 12 days. Service, however, was very costly.

The Habsburgs may have trusted the Thurn and Taxis family, but the rising national monarchies of France and England did not, nor did they trust any other private or nongovernmental message service. The first royal messenger service in France, established in 1464, was reserved for official messages. Private individuals could bribe the royal couriers to carry messages surreptitiously. The royal postal service was opened to the public in the early seventeenth century. It set the rates for private letters very high, to subsidize the official mail.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95056-6

Once the royal mail service was opened to the public, the government attempted to suppress private messengers in order to protect its lucrative monopoly and permit easier surveillance of potentially subversive communications; the last nongovernmental service in France, that of the University of Paris, ended in 1719.

The evolution of the English postal system paralleled that of France. There had long been royal messengers, but the first permanent service was founded in 1512. Royal messages to and from foreign countries, however, were still hand-delivered by special messengers. Meanwhile, merchants had their own networks, such as the Merchant Adventurers' Post for English merchants engaged in foreign trade, and the Foreigners' Post for foreign merchants in England. Queen Elizabeth, suspicious of Catholic plots, ordered all mail leaving or entering the country to be carried by the royal post. This decree, though often repeated by her successors, was never fully enforced.

In 1635, the royal postal service began to serve the public; 2 years later it included foreign mails as well. As in France, 'public service' was a euphemism, for postal rates were kept extremely high as a source of income for the treasury and for the king's favorites and officials who had the right to open and read private letters. Surreptitious inspection of letters, especially those from abroad, was a common occurrence in the eighteenth and early nineteenth centuries. Most people who needed to correspond across borders preferred to send letters with a friend, a servant, a hired messenger, or a traveler. Surveillance abated in the mid-nineteenth century, as the increased volume of mail overloaded the postal bureaucracies.

The mid-nineteenth century saw a tremendous surge in the volume of mail, thanks to two innovations. One was the penny post with prepaid stamps, introduced in England by Rowland Hill in 1840 and soon imitated in other countries. The other was railroads and steamships, which made transportation cheap and fast. Letters from relatives or friends in foreign countries, a rarity until then, became a commonplace experience for middle-class families in the Western world (Headrick, 2000).

Airplanes began transporting mail right after World War I. In parts of the world, such as Africa and South America, that had poor telegraph and rail connections, airmail represented a breakthrough comparable to the effect of railways in Europe a century earlier. In places well served by traditional postal services, airmail competed with the cheapest kind of telegram, the 'night letter.' After World War II, airmail became the standard means of sending first-class postage over long distances.

The Telegraph

Many scholars believe that modern telecommunications began with the electric telegraph. From a technical perspective, the advent of electricity was certainly revolutionary. From an information point of view, however, the revolution began half a century earlier with the optical telegraph, invented by Claude Chappe in France in 1794.

Throughout the French Revolution and after, every French government expanded the optical telegraph network and supported the family that ran it. Chappe and his brothers built lines east to Strasbourg, west to Brest, and north to Dunkirk and Brussels; under Napoleon, they extended the network south to Lyon and Marseilles. As Napoleon's empire grew, lines radiated to Turin, Milan, and Venice, to Antwerp and Amsterdam, and to Mainz. After the defeat of Napoleon the French network was reduced to its domestic lines. Other European countries, as well as the USA, Egypt, and Australia, built individual lines linking their major cities to the nearest harbors. Some of these were government-owned lines reserved for official or military traffic, while others served the merchant communities. In the few instances where two systems met at a border, any message going from one country to the other had to be decoded, translated, hand-carried across the gap, and encoded for further transmission. International telecommunication had to await the electric telegraph (Wilson, 1976; Holzmann and Pehrson, 1995).

During the 1830s, several inventors came up with methods of transmitting information over long distances by electricity. The one that eventually displaced all others was invented by Samuel Morse. Morse's contribution was not the use of electricity but a code which allowed the use of only one wire, with the earth serving as a return. The cost savings of Morse's system made up for the need for trained operators.

During the next two decades, the nations of Europe and North America began installing electric telegraph lines. At first, they used incompatible systems; messages had to be written out, translated, and hand-carried across the border, then retransmitted. As traffic grew, governments strove to overcome this barrier to communication. In 1850, Austria and several German states formed the Austro-German Telegraph Union. Treaties between France and its neighbors followed. Finally in 1865, all European governments except the UK founded the International Telegraph Union, to be administered by the International Bureau of Telegraph Administrations, the first permanent international organization. It encouraged national telegraph administrations to adopt compatible technical standards and to connect their lines across border. By the 1860s, it was possible to send telegrams across Europe and between the USA and Canada (Griset, 1991; Flichy, 1991).

Meanwhile, engineers had solved the technical problems of communicating across the sea. The first successful submarine cable crossed the Channel in 1851. Cables across oceans were a greater challenge, however. The first Atlantic cable failed in 1858, as did the first cable from Egypt to India 2 years later. After many trials and errors, cable technology finally caught up with the demand. The Atlantic cable of 1866 proved reliable. In the 1870s, British companies rushed to lay cables from the UK to India and from there to China and Australia. Cables reached South America and Africa in the 1880s. By World War I, cables criss-crossed all the oceans and connected every continent and every country (Barty-King, 1979; Headrick, 1991; Winseck and Pike, 2007).

Submarine cables were phenomenally expensive, however. Only the North Atlantic had enough traffic to justify several competing cables. In other parts of the world, the high cost of cables had to be amortized over small numbers of customers, and a few firms, most of them branches of the British conglomerate Eastern and Associated, dominated the market. The high cost of sending messages over long distances led business customers and news agencies to develop elaborate code books.

Wireless Telegraphy

Although the telegraph had 'annihilated time and space' (to use a favorite expression of nineteenth-century boosters), it left many people dissatisfied, for both economic and political reasons. Economically, international telegrams were very expensive, and transoceanic ones exorbitantly so, placing them out of reach of all but the wealthiest clients and commercial enterprises. And politically, the fact that most ocean cables belonged to British firms and that most intercontinental telegrams passed through British hands, made all other governments very uncomfortable, especially after 1900, when the UK proved that it was not averse to intercepting, delaying, and censoring foreign messages during a crisis like the Boer War (1900–02).

In 1895, Guglielmo Marconi demonstrated the possibility of transmitting information through space by electromagnetic radiation. He found immediate backing from the Royal Navy and from British shipping lines, which had long wanted to communicate with their ships at sea. France, Germany, and the USA also greeted the new technology with enthusiasm, for they had fallen far behind the UK in the cable business and saw radio as a means of building international connections independent of the UK (Aitken, 1985b).

Until the late 1920s, wireless used longwaves (over 1 km, or less than 300 kHz), which required power in proportion to the distance to be covered; stations powerful enough to transmit across continents or oceans needed dozens of huge towers, miles of antennas, and alternators that used as much electricity as a small town. Within countries, wireless could not compete with the cheap and efficient telegraph networks. Across oceans it was competitive only under unusual circumstances. Before World War I, the four major powers built stations linking them to their colonies. During the war, when it was impossible to lay cables, the US expeditionary force built stations in France to supplement the overloaded transatlantic cables. After the war, to meet the booming demand for transatlantic communications, companies found it faster and cheaper to build gigantic transmitters than to lay costly cables (Aitken, 1985a; Anduaga, 2009).

Longwave wireless had two flaws to which cables were immune: they were vulnerable to atmospheric static and to interception and cryptanalysis. The British, with their heavy investment in cables and their far-flung colonies and bases, were concerned with keeping their cables viable. Thus, it came as a shock when Marconi, the man who had invented wireless, announced a new technology that threatened to make both longwave radio and submarine cables obsolete, namely shortwave radio (*c.*13–120 m or 2.5–22 MHz).

Shortwave, though more vulnerable to atmospheric conditions and less reliable than longwave, had one enormous advantage: it was extraordinarily cheap; a transmitter cost a few 100 dollars instead of hundreds of thousands. Even small inexpensive transmitters could, at certain hours of the day, reach across oceans and around the globe.

The advent of shortwave coincided with the Depression. The collapse in international trade brought the British cable companies to the brink of bankruptcy, but they were rescued at the last moment by their government for strategic reasons. Although cables served a useful function in World War II for the transmission of top-secret information, they were overshadowed by the proliferation of shortwave transmitters throughout the world. Indeed, a war of movement over enormous theaters of war like the Russian plains or the western Pacific would have been inconceivable without a multitude of radios. At the same time, the reliance of armed forces on radio meant that the outcome of battles depended on communications intelligence and cryptanalysis as much as it did on ships, tanks, and planes.

Broadcasting

Broadcasting, the transmission of radio and later television programs to many receivers at once, played a tremendous role in the cultural history of every twentieth-century nation. The first experiments in transmitting voice and music over the airwaves took place before and shortly after World War I. However, broadcasting had little impact on international relations before the 1960s for two reasons. One was that most broadcasting was in the medium wave range (150–600 m, or 500–2000 kHz), which did not carry far; only border regions could receive foreign broadcasts. The other was that programs were in the language and culture of each country (or rather, of each country's elite), with little appeal to foreigners (Douglas, 1987; Anduaga, 2009).

International shortwave programs, such as those pioneered by the BBC in the early 1930s, were specifically designed to appeal to people in other countries. Soon, every major country had its shortwave station beaming news and propaganda to the world, often in many languages. No doubt such broadcasts appealed to the converted and reminded exiles of their homelands, but whether they persuaded more than a handful of foreigners is questionable.

Mention should be made of the interesting cultural phenomenon of ham radio operators who communicated around the world, not so much to convey information as to collect lists of other distant amateurs they had contacted, much as birdwatchers collect the names of birds they have spotted.

Television uses high-frequency waves that cannot bend with the curvature of the earth. Until the advent of satellites in the 1970s, transmitters could only reach local viewers. Satellite television, however, has opened up the world to broadcasts from foreign countries; all that is needed is a dish antenna. Countries with conservative theocratic or tyrannical regimes resent the intrusion of such foreign cultural phenomena as sex, violence, and free speech. However, prohibition is hard to enforce, and people around the world are much more interested in foreign television programs than they ever were in shortwave news broadcasts.

International Telephony

Telephony is a recent phenomenon. Though invented in the 1870s, it affected few people before the early twentieth century in North America, the 1920s in western Europe, and the post–World War II period in other parts of the world; at the

beginning of the twenty-first century, there were fewer telephones in all of Africa than in Manhattan.

International telephony is an even more recent phenomenon. Due to the bandwidth requirements of the human voice, telephone messages could not use telegraph wires, but needed repeaters every few 100 miles. International calls were possible only between adjacent countries. Most telephone systems were government controlled, and calls to foreign countries had to go through an operator and were extremely costly. Calls overseas required two radio stations in each country, one to transmit and one to receive. Until the 1950s, such calls were considered newsworthy events rather than a medium of communication.

This situation began to change after the first transatlantic telephone cable was laid in 1954, and especially after the advent of satellite transmission of telephone calls in the 1970s and fiber-optic cables in the 1980s. As prices fell from dollars to pennies a minute, the number of international calls has multiplied exponentially, with no end in sight. Businesses and even many individuals now make calls to distant countries as readily as their parents once called across town.

As this is written, a new technology promises to change international telephony as dramatically as the first telephone cables: low-earth-orbit satellites that can relay calls to and from portable telephones anywhere on earth, bypassing national networks. Although governments and national companies are likely to resent this intrusion on their monopolies, telecommunications technology is too invasive to stop. Eventually, the well-to-do will be connected around the world, regardless of governments and borders, while the rest of humankind looks on in wonder (Young, 1991; Pool, 1990).

Data Communication and the Internet

The current revolution in communication is as radical as the telegraph's 'annihilation of time and space' that so amazed our ancestors a century and a half ago. By turning text, voice, music, pictures, and video images into bits, electronic digitization allows the transmission of all forms of information with equal ease and speed. Two associated technologies, microwaves and fiber-optic cables, have reduced the cost of transmission almost to zero. The results are nothing short of phenomenal. The first transatlantic telephone cable could carry a dozen or so telephone calls at once; the most recent fiber-optic cables across the Atlantic carry hundreds of thousands of simultaneous calls, or dozens of television channels, or any combination of data, voice, text, or images. Communication is not free because other costs remain, such as switching and distribution. But the price differences between local, long-distance, and international communications are shrinking fast.

The Internet began in the 1970s as a US military project to link the mainframe computers of research institutions. By the mid-1980s, when personal computers began to proliferate, engineers in Europe, North America, and Japan first created simple networks to transmit data, then linked them together into a super network called the Internet that could transmit any information to any connected computer. The demand for this new form of communication soared beyond anyone's prediction, as the public logged onto a virtual world of chat rooms, bulletin boards, electronic mail, shopping, entertainment, advertisements, and even music and video clips from around the world. And the cost is very low. For people who own a computer (even a primitive 'Web-TV' box) this amazing service costs a few dollars a month. All other costs (servers, cables, switches, software, and administration) are borne by governments or by advertisers. The Internet offers telephone and television service and competes with libraries, newspapers, and universities. And unlike the technologies that it replaces, the Internet is oblivious to borders and political jurisdictions. We can only speculate about the effect on cultures and on the politics of nation-states.

Meanwhile, computers, microwave radio transmission, and the digitization of data have revolutionized telephony. Mobile telephones, now in the billions, have reached almost everywhere on earth. Though the first ones carried only voice, newer 'smart phones' connect to the Internet and carry pictures, music, videos, and information of all sorts (Lubar, 1993).

What the public sees is only a fraction of the world of international digital data transmission. Computer networks, connected by fiber-optic cables, have revolutionized finance and commerce as well. Credit-card charges, engineering drawings, business contracts, stock market reports, late-breaking news, banking transactions, and myriad other data flit across the globe at the speed of light. The amount of money – in the trillions of dollars – that circulates at any given moment dwarfs the economies of the largest countries. The new communications media offer the potential for phenomenal economic growth and for disastrous crashes. Humans may still be bound by the laws of physics, but for information, space and time have truly been annihilated.

Abstract

As the International Council on Social Welfare (ICSW) looks back over its past 85 years of history, closely linked to the history of social work and social practice, unfolding across geopolitical borders and aimed at improving the human condition and well-being in the face of socioeconomic uncertainties and risks generated by market-driven societies, the organization recognizes not only its achievements, but also the multiple challenges. For the ICSW, retaining its influence and finding a niche in the new international environment requires much professionalism and dedication and a constant quest of the meaningful, innovative, and cost-effective policies.

The History of the International Council on Social Welfare in Brief

Established in 1928, the International Council on Social Welfare (ICSW) is one of the oldest international nongovernmental organizations (NGOs) aimed at promoting social development, social justice, and social welfare everywhere in the world. The ICSW's history is closely linked to the history of social work and social practice, unfolding across geopolitical borders and aimed at improving the human condition and well-being in the face of socioeconomic uncertainties and risks generated by market-driven societies. While the emphasis placed by the ICSW on international social work and social development, nationally and internationally, has been shifting, the balance between these has evolved. However, a two-pronged approach has been a hallmark since its inception.

The immediate predecessor of the ICSW – the first International Conference on Social Work – was convened in Paris in July 1928. That ground-breaking event became possible following the dedication and vision of several extraordinary personalities willing and capable of assuming leadership in the preparation of the Conference (Among these, the name of the Belgian doctor, scientist, and educator, René Sand (1877–1953) stands out. In 1921, he became Secretary-General of the 'League of Red Cross Societies,' which was created in 1919. Sand endorsed the idea of a large-scale world forum on social welfare in 1923, thereby reviving a proposal floated earlier by Dr Clotilde Mulon at the 46th US Conference for Social Work. Julia Lathrop, the President of the National Conference for Social Work, invited René Sand to address the 50th American Conference on the issue of international cooperation, where he was able to generate a positive reaction to the idea.) in the aftermath of World War I, which brought devastation and suffering to many nations. Preparatory work for the International Conference began in earnest with several meetings of the Preparatory Committee being held over a 3-year period. These culminated in a meeting in Prague in 1927, where the guidelines for the organization of the conference were elaborated and adopted (Le Conseil international d'action sociale, 2008). The stated goals of the conference were fostering discussion and idea sharing between social workers and social welfare organizations from around the world, assistance with dissemination of ideas and professional information, and establishing personal contacts. These efforts promoted international cooperation within the social work profession and beyond, bringing on board numerous activists, experts, and practitioners, and working apart from state-sponsored structures for improving the human condition. The largest intergovernmental organizations of that time – the League of Nations and the International Labour Organisation – provided technical support, with financial backing from several national and regional foundations.

Mapping and identifying the field of proposed activities, the first International Conference in Paris underscored that social work could not be constrained to individual cases but required broad-based interdisciplinary efforts to relieve suffering resulting from want (i.e., providing palliative assistance), to restore people to 'normal' conditions of life (through curative assistance), to prevent social afflictions (preventive assistance), and to improve social conditions and raise standards of living (constructive assistance) (Macdonald, 1975). The importance of individual practice was acknowledged, along with the need to promote legislative and administrative measures targeting a group or community and coupled with research in the fields of social well-being and social welfare. Attempting to delineate a field even further, the participants at the Paris Conference underscored a link between the need to prevent or address social hardships and the availability of resources for social purposes. (Premiere Conference international du service social, Paris, 1928, tome I, 1929, Statuts, pp. 25, 172.) There was agreement on the need for professional qualifications and skills, but opinions among more than 2500 participants, who represented a diverse group of social workers, health care providers, welfare officers, and other activists, differed as to the respective roles of the state and private institutions. The variety of views was also reflected in the submissions of national committees and in publications of the executive committee, even though there was an agreement about the basic values of international social work practice and the general directions as outlined above.

Since the first conference, the importance of the thematic approach was recognized; the first priority theme was 'Social Work and Industry.' About two-thirds of the participants at the Paris Conference were women. The Conference elected a woman – Alice Masarykova, the President of the Czechoslovakian Red Cross – as the first President of the ICSW for 4 years.

Doctor René Sand became the first Secretary-General of the International Conference on Social Work, a post he held from 1928 to 1932, after the Provisional Preparatory Group of the Paris Conference transformed itself in 1928 into a permanent organization under the name "International Conference on Social Work" (Eilers, 2003).

The aim of this move was to capitalize on the positive momentum and translate the wealth of ideas that had emerged at the first conference into practice so as to continue its activities without any interruption. René Sand became President in 1936 and held that position until the outbreak of World War II (WWII). Having become a permanent organization, the International Conference on Social Work represented national councils on social work and social welfare, promoting humanistic values and advocating for disadvantaged population groups, and also assisting its members with information and consultative work. At the same time, recognition of the substantial differences in approaches taken at the national level and counterproductive responses to encouraging the same strategy for everyone led to acceptance of the substantial autonomy of each organization (Le Conseil international d'action sociale, 2008, p. 16).

Before WWII, two international conferences were convened with a 4-year interval – in 1932 in Frankfurt, Germany, on the topic 'Social Work and the Family,' and in 1936 in London, UK, on 'Social Work and the Community.' The ICSW global conferences resumed in 1948 after the interruption caused by WWII. Since that time, the global conferences of the ICSW have been held periodically, initially every 4 years, and since 2010 every 2 years. Global conferences on social work and social development were organized through close collaboration among the ICSW, International Association of Schools of Social Work (IASSW), and International Federation of Social Workers (IFSW) – the three sister organizations as they have been termed. (In 1929, an International Committee of Schools of Social Work was established to give prominence to the specific needs of social work education, explore best practices, and facilitate international cooperation; the first conference of IASSW was in 1929 in Berlin. The first conference of IFSW was held in 1956 in Munich, at the same time as the ICSW conference (see Le Conseil international d'action sociale, 2008, p. 50).)

The international conferences regularly convened by the ICSW either separately or together with IASSW and IFSW have dealt with recurring issues and new subjects that reflected political realities and deep changes on the global scene. During the 1950s and 1960s, the emergence as independent political actors of a large group of developing countries facing entirely new social and economic challenges caused the ICSW to recast its agenda on socioeconomic development to encompass social rights, social welfare, and well-being, including dominant policy discourses around the improvement of the lives of those living in poverty, participation, social cohesion, community development, and growing significance of social services. These have become a constant feature of the global discourses on social issues, gradually expanding the scope and objectives of social welfare goals, analyzing interaction of key actors, and presenting analysis of policy instruments (Gough, 2004). The membership of the ICSW expanded, as national councils from many developing countries in Asia, Africa, and Latin America became members.

Organizational adjustments followed, and in 1966, the ICSW – which until then was known as the 'International Conference on Social Work' – changed its constitution and name to the 'International Council on Social Welfare,' without having to change its English acronym, ICSW. Commenting on that change, Kate Katzki, the Secretary-General (In 1996, the position of the 'Secretary-General' was renamed the 'Executive Director.') of the ICSW from 1967 to 1988, underscored the fact that the ICSW could no longer focus on only one single goal, namely, an international forum for discussion among social workers. (Kate Katzki, 60 years of ICSW, New York, 1988, p. 16 quoted in Le Conseil international d'action sociale, 2008, p. 32.) The name change reflected the profound structural changes in the organization, the growing diversification in its activities, and the higher political profile sought by the ICSW leadership.

Structure and Organization of Activities

According to the Constitution of the ICSW, (The most recent constitution was adopted by the Committee of Representatives on 29 December 2007, and amended on 14 June 2010. The Committee of Representatives itself was given a new name of 'General Assembly,' retaining the same duties and prerogatives.) "the Council" is a "global, non-governmental, non-political, non-sectarian and non-profit organization which represents a wide range of national and international member organizations that seek to advance social justice, social welfare, social work and social development" (The ICSW Constitution, clause 1).

The primary objectives of the Council are as follows: Promote forms of social and economic development that aim to reduce poverty, hardship, and vulnerability, especially among disadvantaged people; strive for recognition and realization of fundamental rights to employment, income, food, shelter, education, health care, and security; promote equality of opportunity, freedom of expression, freedom of association, participation, and access to human services and oppose discrimination; promote policies and programs that strike an appropriate balance between social and economic goals and that respect cultural diversity; strengthen civil society throughout the world to achieve these objectives; seek implementation of these objectives by governments, international organizations, and nongovernmental agencies in cooperation with its network of member organizations. (The ICSW Constitution, clause 1.)

The *General Assembly*, which adopts the 4-year global program and the 2-year budget framework, is the supreme governing body of the Council, electing the President, Vice President, Treasurer, and other members of the *Management Committee*, responsible for all matters not specifically allocated under the Constitution to the General Assembly or to the *Supervisory and Advisory Board*, which comprises the Regional Presidents, the President, the Vice President, and the Treasurer. It is entrusted with supervision and monitoring the *Management Committee*, creating and amending the bylaws, and establishing and restructuring regions. (The ICSW Constitution, clause 9, 10, and 11.)

While the ICSW is a worldwide nongovernmental organization with regional structures, it is not a mass organization, and only one national council from each country can be accepted into membership. The regional organizations are indigenous to the regions. The regions play an active role, but membership is assumed directly with the international headquarters, and not via regions. The ICSW is a unified organization that could be compared to an amalgam rather than a mosaic as far as its membership is concerned. (ICSW membership is classified into several different categories. Category A covers national committees having a broadly based membership in their respective countries and seeking to enhance social justice, social welfare, social work, and social development in that country. Category B is reserved for international nongovernmental organizations trying to achieve the same objectives. Categories C and D are intended for civil society organizations that cannot claim to work on a full range of issues and be the key party representing social welfare issues in the country, but seeking to enhance social justice, social welfare, social work, and social development anyway. (The ICSW Constitution, Clauses 5–7).)

The regional structure is established under the bylaws, and regions have their own decision-making bodies, as well as their own programs of activities. Each member, with the exception of International Member Organizations, is allocated to a region by the Board for the purposes of the allocation of membership fees, and each member is entitled to the same rights in the region as globally. At the same time, there is substantial organizational flexibility – any member organization is able to cooperate with any member organization in other regions, as well as, by agreement, participation in other regional meetings, activities, and ICSW structures. Regional General Assemblies and other regional organs have been established under global and regional by laws. (The ICSW Constitution, clause 8.) Some regional entities have their own legal status separate from the ICSW.

The President of the ICSW is the highest elected official and representative of the Council and is elected to a single 4-year term, without the possibility of a second consecutive term. In his capacity of the strategic leader of the organization, the President sets overall direction and proposes innovative policy solutions, maintaining interaction with other partners and stakeholders at the regional and global levels.

The ICSW Executive Director is responsible for implementing the decisions of the General Assembly, Board, and Management Committee and for keeping the Management Committee informed on issues that are important to the proper functioning of the organization. The Executive Director combines supervision of the day-to-day operations of the Global Office with substantive outreach activities, editing the Global Cooperation Newsletter published by the ICSW in English, French, and Spanish, and maintaining links with various partners, including other NGOs and intergovernmental organizations.

The ICSW has consultative status with the United Nations Economic and Social Council (UN ECOSOC), International Labour Organization (ILO), and other UN agencies. This status enables the ICSW to address UN bodies through broad-based statements and advocacy, participate in the intergovernmental discussions, and present recommendations to intergovernmental bodies. The ICSW's Global Programme is a strategic framework of the organization designed to operate at the global, regional, and national levels, setting the goals and umbrella policy for the Council operations for 4 years.

Expanding the Scope of Work at the Global Level

Through the years, the priorities of the ICSW have been changing, reflecting the political changes in the world, the development and refinement of a global perspective in its work, as well as the growing awareness of the need to reconcile social and economic policy. In the face of the progressing integration and liberalization of the world economy and the new intensity of international competition – with its profound, and not necessarily positive, effect on social spending and delivery of social services – the welfare situation has varied significantly from one region to another, with growing uncertainty at the local, national, and regional levels and widespread setbacks in living standards.

The development discourse has also not been static. Human development has emerged as one of the central concepts in international development since the early 1990s, supported not only by civil society but also by many governments and international organizations. The need to view people as the ends of development as well as its means, focus on both poor and the poorest people, and prioritize capability enhancing services (such as food security, education, and health), and the multidimensional conceptualization of human well being and poverty have shifted the focus of many economists and policy makers away from the earlier emphasis on per capita economic growth as the sole indicator of socioeconomic progress. The 1990s marked a watershed in the evolution of ideas about poverty reduction (Hulme, 2007).

At the onset of the 1980s, the ICSW had three core priorities: convening conferences and ensuring space for discussions, providing support to national committees, and building stronger relations with the UN. The situation changed in the late 1980s and early 1990s, when a more comprehensive agenda emerged both at the ICSW headquarters and in the regions, covering such themes as access to the means required for economic independence, strengthening social infrastructures, the issue of violence and social development, and the social dimensions of technological change. Suggestions were made to go further and address on a consistent basis topics such as the significance of aging, human immunodeficiency virus/acquired immunodeficiency syndrome pandemics, and North–South relations. In the 1980s, a gradual shift in the philosophy of the organization became apparent, including its main thrust from the idea of 'social work' to 'social welfare' and then to 'social development' (Le Conseil international d'action social, 2008, p. 45).

A deliberate and consistent move was made in the 1970s and 1980s to go beyond social work and enhance social development dimension in its global activities and broaden the scope of ICSW's activities. The interdisciplinary and holistic nature of the ICSW approach to development thinking formed after WWII and was vividly demonstrated at the ICSW global conferences. The ICSW has been invited to take part in numerous conferences, expert group meetings, research

seminars, and other events of international significance, to share its experiences and provide substantial inputs. Its global image was strongly reinforced during the preparation of the World Summit for Social Development (WSSD) convened in Copenhagen in 1995.

The preparatory process of the WSSD provided the ICSW with an opportunity to present its analysis and vision of the world social situation to influential global audiences. First of all, the ICSW actively participated in the work of the preparatory committees for the summit, promoting in accordance with its Constitution forms of social and economic development that aimed to reduce poverty, hardship, and vulnerability throughout the world, and making specific suggestions regarding ways to ensure the progressive realization of all human rights, including economic and social rights. Apart from discussions at intergovernmental meetings, deliberate efforts were made to link closely the activities of the ICSW with the preparatory process for the Summit. For example, the Tampere Manifesto adopted by the 1994 ICSW global conference was conceived with the Summit agenda in mind; the document advocated "an integrated and integrative approach to social development," promoted rights to equal opportunities, supported grassroots initiatives, and strongly condemned violence, intolerance, and xenophobia. It also addressed the priority themes of the WSSD: poverty eradication, employment promotion, and social integration, and was submitted to the Preparatory Committee. (Le Conseil international d'action sociale, 2008, pp. 70–71. Summing up the ICSW's contributions and addressing the Plenary Session of the World Social Summit in Copenhagen on 7 March, 1995, ICSW President Dirk Jarré indicated that the Council "has been actively and constructively involved in every phase of the preparatory process leading to the Summit. We have mobilized our global resources—in personal, intellectual, organizational and financial terms—to inform NGOs about the Summit and to motivate them to participate in the endeavour, to contribute ourselves directly to the Summit's content and to give support to the process itself" (Address to the Plenary Session of the WSSD by Dirk Jarré, 1996. In: Social Priorities of Civil Society. Speeches by Non-Governmental Organizations at the World Summit for Social Development, NGLS, New York, p. 60.).

The WSSD represented an important political threshold for the ICSW, not only in terms of opportunities to contribute to the outcome documents but also by the fact that it became an important benchmark for ICSW-affiliated organizations during the implementation phase; in many ways ICSW activities in the post-Summit period became aligned to the Ten Commitments made in Copenhagen and the recommendations of the Plan of Action adopted at the Summit. The principles of social justice, equity, and equitable societies, high on the WSSD agenda, are shared by the ICSW, which has been striving for many years to put these principles into practice on the ground and promote them in high-level international forums. Creating an environment to enable achievement of social development, eradicating poverty through decisive national action and international cooperation, promoting full employment as a basic priority, and fostering stable, safe and just societies to promote social integration – all those commitments that emerged at the Summit have been taken on board as guiding principles by the ICSW in its own activities. The global consensus reached at the Summit that poverty eradication should remain a priority goal for development was a crucial element that gave a forward momentum to several new post-Summit initiatives, including the elaboration and adoption of the Millennium Declaration approved on 8 September 2000, and the elaboration of the Millennium Development Goals (MDGs) a year later based on the Millennium Declaration where the eradication of extreme poverty and hunger were put on the top of the list.

The ICSW also actively participated in the preparation of the twenty-fourth special session of the General Assembly convened in Geneva in June 2000, where the commitments of the WSSD were reviewed with respect to further action and initiatives. As a follow-up to the WSSD, the ICSW has participated in all of the annual sessions of the Commission for Social Development (CSocD) – one of the functional Commissions of ECOSOC, which reviews the outcome of the Summit every year. The written and verbal statements made by the ICSW representatives highlight the efforts of the ICSW-affiliated organizations in the context of the implementation of the Summit commitments and increased priority that social development has assumed vis-à-vis other policy objectives.

Some key topics and crosscutting themes raised in the statements could be mentioned. Depending on the context of the discussions and the priority theme of the CSocD and in line with ICSW objectives, the ICSW statements addressed issues such as the urgent need of an integrated approach to social development, the missing links between strategy and policy, called for more focused policies aimed at the equitable distribution of resources and opportunities. Reflecting the spirit of the World Social Summit, the statements made by ICSW representatives sought to highlight the goal of poverty eradication and draw attention to the role of employment as the nexus between economic and social policy and the plight of the working poor and the need to address growing inequality within and between nations. The ICSW consistently speaks for social inclusion and promoting 'a society for all' – a goal identified by the WSSD as one of the core priorities.

Promoting social protection as one of the pillars of a forward-looking social policy has become one of the key priorities and recurrent themes in ICSW advocacy efforts. The shift away from universal, publicly provided social protection schemes to needs-tested targeted assistance, which became evident with spread of neoliberal economic policies, encouraged by the international financial institutions has been extremely painful for many societies. ICSW efforts have sought to draw attention to the existence of positive alternatives to targeting, and the detrimental dimensions for well-being of the 'race to the bottom' resulting from cuts in social spending; and advocate consistently for the principles of the universal public provision of basic social services and basic income. Protecting people against contingencies and risks, along with developmental and social justice functions of social protection are well known (Department of Economic and Social Affairs. Report on the World Social Situation 2001. United Nations, New York, 2001, p. 217.) and have always been underscored by the ICSW in its policy statements.

The new impetus to these efforts was provided when Recommendation 202 on national floors of social protection was adopted by the International Labour Conference at its 101st session in 2012. There is increasing recognition of the fact

that the implementation of nationally defined social protection floors (SPFs) may be regarded as an important tool in the fight against poverty and inequality. A rights-based approach aimed at protecting women, men, and children from risks and vulnerabilities helps to sustain their well-being throughout the life cycle, guaranteeing access to health care and other basic services, as well as at least a basic level of income security. The ICSW has supported that initiative since its inception by the UN in 2009. (See the ICSW Statement on Poverty eradication, Commission for Social Development, Fiftieth session.)

Joining forces with more than 60 other NGOs, the ICSW formed a Global Coalition for Social Protection Floors, which has an increasingly important role to play in shaping the debate, raising awareness, achieving a national consensus on policy priorities and monitoring progress of SPFs. But the coalition with NGO partners is not the only joint effort undertaken by the ICSW in connection with social protection promotion. Among a limited number of other international NGOs, the ICSW has been invited to take part in the work of the Social Protection Inter-Agency Cooperation Board chaired jointly by the ILO and the World Bank. The Board has been instrumental in considering social protection in the context of the deliberations on the post-2015 development agenda when the existing MDGs expire, interagency work at the country level, cooperation in the field of social protection statistics, and other key issues linked to social protection promotion.

Another important partnership was formed by the ICSW at the UN with civil society organizations working to promote the rights of older persons. The ICSW has been closely collaborating with the Global Alliance for the Rights of Older People, voicing its support for the elaboration of a new legal instrument to protect the rights of older persons. Despite its undeniable importance and wide-ranging socioeconomic consequences, population aging is one of the issues that has not been addressed in the framework of the MDGs. In that light, the role of the Open-Ended Working Group on Ageing (The working sessions of the OEWG were convened twice in 2011, and once in 2012 and in 2013.) established by the UN General Assembly in December 2010 to consider the existing international framework for the human rights of older persons and to identify possible gaps and how best to address them, including by considering the feasibility of further instruments and measures, is the most important. Its significance as a new and influential international forum on aging and development should be recognized, particularly given the fact that aging presents a challenge not only for the developed countries but also for the developing world. Since the inception of the Working Group, the ICSW has actively participated in the discussions, which have covered numerous political and socioeconomic aspects of population aging at the national, regional, and international levels, highlighting both the emerging issues and the opportunities presented by aging, but always dovetailing around its original declared objective – how to protect better the rights and interests of older persons.

Participating in the deliberations, the ICSW has not only submitted official statements (See ICSW statements to the Open Ended Working Group at the third and fourth sessions in 2012 and 2013, respectively: http://social.un.org/ageing-working-group/.) but also usually provided ad hoc comments during the discussions, making specific suggestions on how to move the process forward for the benefit of older persons. The importance of clarifying the scope and content of human rights norms has been stressed, given the fact that non-implementation of the existing standards is rampant, even though in many cases and particularly in developing countries those standards are themselves quite low, remaining inadequate for the effective protection of older persons. (See, for example, OHCHR. Normative standards in international human rights law in relation to older persons. Analytical outcome paper. August 2012.)

Apart from ties built within the UN environment, the ICSW has also built a strong collaboration and partnerships with sister organizations that have the same historical roots, namely, with the IASSW and IFSW. The three organizations work together to produce the *International Social Work* journal, and collaborate in organizing joint world conferences on social work and social development issues every 2 years. The conferences provide ample opportunities for the stakeholders to discuss issues that the social work and social welfare sectors face on everyday basis and to ensure a closer link between evidence-based practice, policy objectives, and social development goals. Furthermore, the joint global conferences have revealed how actions geared on accomplishing the priority goals of the joint Global Agenda adopted by the ICSW together with IASSW and IFSW might impact on the conditions of people and demonstrate how actions by the social work and social development community can contribute to an enduring physical environment, promote compliance with a range of climate-related policies and measures, and help raise awareness and build capacity among practitioners regarding the imperatives of sustainable development.

Coming together in Paris in mid-November 2012 to consider specific actions in the context of the implementation of the Global Agenda, the three partner organizations decided to establish a Global Agenda Observatory to gather evidence about the activities of social workers, educators, and social development practitioners who support the implementation of the Global Agenda and to give visibility and credibility to their contributions and promote further action. This new entity is structured around the four themes of the Global Agenda commencing with the theme of promoting social and economic equalities. The themes to be covered in subsequent years include promoting the dignity and worth of peoples, working toward environmental sustainability, and strengthening recognition of the importance of human relationships. A focus on ensuring an appropriate environment for practice and education will be maintained throughout. (The Global Agenda Observatory is conceived as a mechanism for monitoring and reporting upon the implementation of the Agenda Commitments and will consist of networks or consortia composed of institutions of higher education and professional/practice-based organizations that jointly conduct research, analyze, synthesize, and report on Agenda activities. It also involves a process that will evolve over time. It aspires to establish a strong, credible monitoring mechanism over the next 10 years. The Global Agenda Observatory will be established at the local, national, regional, and international levels, working through the existing structures and work plans, taking into consideration the existing priorities of each of our organizations.)

Regional and National Activities

At the regional level, the ICSW seeks to increase the consideration of social development by regional groupings of governments; at the same time, at the national level, the ICSW works to strengthen the ability of national councils to influence social policy and programs in their respective countries, taking into account local conditions and priorities of national socioeconomic development.

Activities covered by the national councils are wide-ranging, but within the remit of the ICSW Global Programme. For example, in 2012–2013, regional activities of the ICSW-affiliated organizations in Latin America concentrated on the affordability of social protection and the feasibility of the SPF initiative, exploring the new tools and policy measures. In Asia, activities covered issues of applicability and affordability of social protection schemes to the specific regions (South Asia), highlighted the importance of partnerships and collaboration among governments and NGOs on social welfare matters (Southeast Asia and the Pacific), and explored challenges of aging and long-term care (Northeast Asia).

ICSW Europe has convened seminars to explore the situation of the working poor, people who have been pushed into the lower end of the job market. Their plight represents a growing concern in countries at all levels of development, including economies in transition and developed-market economies.

In June 2013, the ICSW in the Middle East and North Africa Region organized a high-level forum on the importance of national civil dialogue, where issues of social inclusion and participation were discussed, along with finding ways and means to ensure that the 'voices' of various groups in society are heard, giving real substance to the concept of citizenship and democracy. The event was extensively covered by the regional press and other mass media (Le Matin, Rabat, 13 June 2013). In the African region, ICSW activities focused on capacity building, promoting partnerships, and addressing resource mobilization issues. (One of the most innovative projects in the context of promoting North–South partnerships is the joint project between the Tanzanian Council for Social Development and the Finnish Federation for Social Welfare and Health. (recently renamed SOSTE), which aims at regional capacity-building programs to strengthen national councils to be effective advocates for social development and poverty reduction.)

The ICSW training program to strengthen national councils is an integral part of its ongoing work, representing a combination of bottom-up and top-down efforts. Apart from capacity development, training sessions organized by the ICSW provide opportunities to strengthen existing links with the academic community and to build new knowledge-based networks.

Conclusion

As the ICSW looks back over its past 85 years of history, the organization recognizes not only its achievements, but also the multiple challenges. The number of NGOs dealing with social development issues has mushroomed during the last 20 years. For the ICSW, retaining its influence and finding a niche in the new international environment requires much professionalism and dedication, and a constant quest of the meaningful, innovative, and cost-effective policies.

Abstract

This article examines single shared assessments in social work practice, promoted as a means of reducing duplication, cutting bureaucracy, providing a single lead point across services for assessment, and addressing the needs of people who use human services. The development of the single shared assessment process and its location with social work assessment, policy, and legislation in the United Kingdom is described and the technology is critiqued.

Introduction

This article explores the developing concept and practice of 'single shared assessment (SSA)' or 'Single Assessment Process (SAP)' as it is emerging within social work, particularly in the United Kingdom, but akin to other models of integrated service delivery such as that in Quebec, Canada (Hébert and Veil, 2004). The SSA primarily relates to assessments that are shared across various agencies. Social work processes are adaptive, moldable constructs, and the assessment and interventive practices that are currently employed not only differ within the separate UK administrations, as well as internationally, but also are dynamic and changing as sociopolitical developments and social work, as it is locally embodied and enacted, interact to build received practices.

The article will provide an overview of assessment in social work practice, locating it as a central element globally of the social work process. It will identify some of the types and meanings associated with assessment and explore the political rationale that drives much of it, and of which social workers should be aware if they are to act alongside, with and on behalf of people who use their services.

Social work's central role in assessment will be highlighted but this will be problematized as government policy seeks to create human profession isomorphs in conducting assessment that may leave out the unique contribution of social work to enhancing people's life chances and choices. However, these conflations have credence within policy and guidance and the evolution of SSAs and their deployment will be explored and critiqued as both recognition of the centrality of the person-in-environment as expert and the isomorphic tendencies of marketized human services bureaucracies.

Social Work Assessment in Context

The notion that assessment is a key task in social work practice has long been recognized (Hollis, 1964; Pincus and Minahan, 1973) and yet there has been very few attempts to construct or provide a systematic conceptual and theoretical base for assessment (Clifford, 1998) with an increasing reliance on instrumental and functional approaches (Martin, 2010).

There may be agreement that assessment is central to social work; there is dissension on what assessment actually means, how it should be conducted, who should do what with it, and with whom it should be done. These reflect social, political, organizational, and practice-based questions that have, over time, assumed a more overt focus on 'risk' and its identification, aversion, acceptance, or mitigation. Perhaps this, in part, results from the desire to move away from the traditional, essentialist approach promoted by Mary Richmond who borrowed scientific language and method in her *Social Diagnosis* (1917). Also, the rejection of positivist thought in social sciences in favor of fluidity and uncertainty (Clifford, 1998) has continued the debate. The purposes of assessment are as varied as the methods designed for undertaking them. While a systematic theory of assessment has not been produced, it could be argued that the dynamic and fragmented interactions of human lives are better served by a theoretical orientation that allows difference and change rather than an attempt at rigorous definition (Milner and O'Byrne, 2009).

Risk has always been part of social work assessment as it has been part of the social work process itself; whether assessing the risk of the 'undeserving' gaining charitable alms, the risk of significant harm occurring to a child, or the risk a person with mental health problems presents of injuring themselves or others. However, risk has become 'concretized' as an entity that is believed to be subject, potentially, to accurate calculation and, thereby, mitigation. Risk assessments have come to represent regulatory technologies of practice, working to protect the professionals rather than service users (Dominelli, 2004). It is something with which social workers must grapple, while understanding its temporally fluid, socially constructed status, and recognizing some of the tensions arising from a risk focus that may work against the wishes of those with whom social workers engage from child protection to adult social work (Littlechild, 2008; Parker, 2013). A paradox of injustice may, indeed, arise from uncritical application of risk assessment in social work (Reamer, 2001).

Many models are linear, prescriptive, and stylized in a way that failed to meet the needs of contemporary social workers (Milner and O'Byrne, 2009). Examples abound within government frameworks often sporting large number of questions and areas to undertake an assessment. The lack of theoretical base may be construed as a weakness in social work highlighting the focus on instrumentality and

a disjuncture between social workers' understanding of complexity and social policy and guidance promoting normativity. Focusing on an holistic assessment of the person-in-environment challenges such instrumentality allowing concerns for social justice to emerge (Healy, 2005), something that Dominelli (2012) has extended.

Part of this definitional debate concerns the perceived dichotomy between social work as an 'art' or as a 'science.' The debate is well rehearsed in the literature (England, 1986; Parker and Bradley, 2010). A measured approach would suggest that social work is both an art and a science since it integrates skills and 'professional' knowledge in its application.

Assessment is popularly understood in terms of judging or valuing the worth of something. This is indicative of an objective activity. It implies the use of standards against which something can be appraised. This certainly appears to be the case in many social work assessments. However, it leaves out the interactive nature and consideration of the person assessed, which also feature in social work assessments (Wilson et al., 2011).

Assessment in social work is also firmly rooted in the context of social work values calling for an explicit acknowledgment of their influence. Social work assessments, therefore, combine the judgment of something with the explicit acknowledgment of the importance of values, diversity, and the views of others. One way of examining assessment in social work is to separate the 'types' of assessment used.

Social work assessments can be separated into two basic types. First, as an ongoing, fluid, and dynamic process (Coulshed and Orme, 2006; Parker and Bradley, 2010). This develops the 'what and how' that needs to be done. It is something that continues over time and aligns with social work as an integrated process (Compton and Gallaway, 1975; Dominelli, 2004). Assessments may also be evaluative and reflexive continuing through the process of social work (Hardiker and Everitt, 1996) and specifically when working with sexually abusive young people (Hackett, 2004). Bartlett and Saunders (1970) consider the assessment process to represent an intellectual exercise that, aligned with professional judgment, can promote holism and social justice (Healy, 2005). However, social workers often do not continue the assessment throughout a planned piece of work. In fact, UK community care legislation and practice may preclude such a continuous process because of the separation of assessment as a discrete activity. Assessments in child protection may also be undertaken as a time-specific formulation that, when employed instrumentally, focuses on function rather than on individuals and acts to protect social workers rather than working on behalf of service users (Lloyd and Taylor, 1995; White et al., 2010). This has ramifications for the ways in which SSAs are both construed and conducted.

This latter kind of assessment suggests norms and standards. It offers a way of examining a situation, event, or individuals at a specific period in their lives and making predictions or identifying needs, goals, and ways of achieving these. Time-specific assessments, at times, offer a baseline, from which change can be continually monitored. It does not, however, necessarily give the assessor the depth of information they need, and it may reflect the values of those making or commissioning the assessment rather than those being assessed.

The levels at which assessments are conducted may be broad-based and holistic or focused on a particular issue serving to inform a particular intervention. These levels do not preclude one another. It may be appropriate in many circumstances to undertake a broad social assessment prior to focusing on an agreed goal and target for intervention that may demand a much more specific focus and activity. In practice, social work assessments often not only reflect different levels throughout the intervention but contain elements of both types identified above. Being explicit about the type used and the implications of this for the clients or service users is important (Fook, 2012).

It is important to acknowledge the differential and varied impact that legislation, policy and procedure, and the theoretical orientation, beliefs, and values of practitioners have on the practice of social work assessments (Milner and O'Byrne, 2009; Parker and Bradley, 2010). It is also imperative that workers be aware of and check their individual bias and how this may well affect the assessment undertaken. A degree of reflexivity, reflecting on how one reflects as a social worker, allows social workers to question practice and outcome in assessment, allowing challenges to received wisdom (Taylor and White, 2001).

Social work assessment serves to reach initial conclusions that describe, explain, predict, evaluate, and prescribe interventive methods. Thus, it has a purposive element. Traditionally, assessments have followed resource-led pathways rather than the broader needs-led approach. The needs-led approach separates out ends and means and is not meant to be dependent upon available resources. However, Coulshed and Orme (2006) indicate that needs-led principles cannot work unless there are plenty of resources and that in social work there are likely to be situations where demand exceeds supply.

A social work assessment is a focused collation, analysis, and synthesis of relevant collected data pertaining to the presenting problem, identified needs, and a pertinent to agency function both prior to and during planned and purposeful intervention (Parker and Bradley, 2010). All social work assessments, therefore, run the risk of inducing normative behavior and need to be 'troubled.' It is important that assessment is not seen simply as an activity, skill, or practice that can be undertaken in a linear fashion without recognition of theoretical and philosophical underpinnings and the importance of working together with those who use services (Hepworth et al., 2009). Grouping the ways in which assessment can be understood can help social workers to develop a questioning, critically reflective appreciation of the meanings and possible impacts assessment can have on individuals. The following model groups assessment around prescribed and political approaches, 'tribal' allegiances fostered by theoretical ideologies, and processes or rituals involved in the 'dance' or interrelational conduct of assessment.

1. Frameworks and regulatory frameworks – (political assessment), for example, Common Assessment Frameworks, the SSA process (see Turney et al., 2011)

2. Theoretically influenced assessment – (tribal assessments), for example (Payne, 2005; Milner and O'Byrne, 2009),
   a. Evidence-based practice
   b. Psychodynamic assessments
   c. Cognitive-behavioral assessments
   d. Person-centered assessments
   e. Community assessments
3. Procedural assessment – (ritual – liturgical or prescriptive)

Understanding and critiquing the assessments employed by agencies and organizations and the ways in which these are conducted (Smale et al., 1993; Preston-Shoot, 2012)

4. Interpersonal assessment – (ritual – relational)

Critical reflection on the interpersonal processes involved in assessment (Ruch, 2013) – data choice and gathering; data analysis and interpretation; the impacts of relationship.

The SSA model can align to all the above types. While politically determined, prescribed, and driven, it is possible for individual practitioners to engage with individuals, to recognize theoretical and personal biases and to engage with others rather than 'apply' an assessment.

What People Who Use Social Work Services Want and Say

User voice and involvement in the process of assessment has influenced the development of new approaches that recognize the importance of the participant, moving them from a passive subject status to an active participative one (Doel and Best, 2008). This, in part, has led to the development and promotion of SSA processes.

Early work concerning the user voice highlights two particular concerns; first, the quality of the relationship with the practitioner and, second, the effectiveness of the services received (Mayer and Timms, 1970). To achieve these requires planning. Planning involves making a comprehensive and careful assessment formulating goals and developing a sequential program aimed at achieving these goals while choosing methods and establishing criteria against which the outcome can be evaluated. However, in the task-oriented approach to inclusion that this may foster, it is central to maintain a clear emphasis on relationship (Ruch, 2013).

With variations in emphasis, the consumerist approaches to involvement from the political Right, to the activist approaches of the political Left, there has been a focus on aspects of clarity, honesty, openness, accountability, and efficacy in the relationship. It is the latter, however, which permeates the debate. This is taken up by Ruch (2013) as an important aspect of any assessment. If the SAP or SSA is to work, it is crucial that a constructive working relationship is formed, and important that this human interaction in the complex arena of assessment is allowed to mitigate the normative effects of instrumentality and standardization in the process.

There is an element of control involved in assessments especially when these are carried out by statutory social services agencies. Not only do they control access to services but also tend to control, exercising power over the disadvantaged sections of society (Ney et al., 2013). It is essential, therefore, to be accurate in factual content, and to recognize subjectivities as these may conceal normative values applied through the assessment process. In this regard, systematic and multiple source data collection methods help. It may be construed that SSAs could assist here, as they will triangulate interpretation from different disciplinary perspectives.

Smale et al.'s (1993) tripartite model of assessment offers a perspective on the ways in which SSA may be undertaken: as a 'questioning model' that emphasizes the expertise of the social worker; a 'procedural model' that emphasizes agency function and may employ checklists that demand little professional judgment or critical thinking; or an 'exchange model' that recognizes that people are experts on their own problems. The emphasis is on an exchange of information and mobilizing individual strengths to meet agreed goals.

Multidisciplinary assessments were developed as a potential safeguard in community care, the purpose of which is to create individual and flexible packages of care from a range of service providers, agencies, and groups. It is partly these laudable aims that led to the concept of SSAs across many countries. This process should be undertaken in conjunction with clients, seeing them as 'experts' in respect of their own situations (Preston-Shoot, 2007).

The Single/Shared Assessment Process

It is important to understand the context in which social work assessment has developed as it provides the sites in which SSA has developed, such as the search for inclusion of the user voice, multidisciplinarity, a reduction of the burden of telling the story, and recognition of the complexity of human situations. It also provides a significant role for social workers as lead professionals who coordinate assessment acting as the central point of contact for service users and professionals alike. However, the concept(s) of SSAs are not quite as they seem and require a degree of critique, something recognized early by Glasby (2004). In this article, examples from the United Kingdom will be used to illustrate potential learning for social work globally.

The New Labour Government in the United Kingdom made partnership working a key priority from 1997 onward, despite the undeveloped evidence base in its favor (Miller and Cameron, 2011). The development of an integrated comprehensive assessment; a SSA; or Single Assessment Process/Tool has been part of the overall vision for health and social care services in the four administrations of the United Kingdom since 2001 at least. Challis et al. (2010), however, trace concern for comprehensive, holistic assessments to the heady age of the birth of the Welfare State in Britain (Warren, 1946). Terminology remains contested and to an extent confused and differentiated, reflecting the different levels adopted in pursuit of the process. In this article, the various terms will be used interchangeably reflecting country preferences, but there will be inclination toward SSA and SAP.

A key aim of the SAP, in the United Kingdom, was to standardize the assessment processes for older people among professionals working in health and social care. An underlying principle was also to promote independence for older people – a principle that was pronounced in key policy documents (Department of Health, 2000, 2001). This approach has been challenged to an extent by older people themselves whose experiences of the SAP indicate a need for interdependence recognizing the limits to self-responsibility (Powell et al., 2007), and hinting, no doubt, at the unspoken politicoeconomic agendas underpinning pursuit of independence. There have been delays in operationalizing the process and the SAP, although designed to be implemented by April 2004, has been integrated in a patchy and nonstandardized way nationally (Tucker et al., 2007). There also remains division between health and social care agencies based on cultural barriers and different funding streams (Miller and Cameron, 2011).

Assessment in adult social care in the United Kingdom is located in a system of care management. Concerns for escalating costs and belief in the efficiency and appropriateness of care within the person's own home led, following the Griffiths Report (1988) and White Paper Caring for People (Department of Health, 1989), to legislation in England, the National Health Service and Community Care Act 1990, and subsequent guidance which, in turn, heralded the care management system.

In part, the introduction of the SAP, was a government response to earlier criticisms of multidisciplinary working within the context of care management (Manthorpe et al., 1996). The aim of the SAP was to "promote better care services and better outcomes for older people, and more effective use of professional resources." Particularly, the SAP "should ensure that the scale and depth of assessment is kept in proportion to older people's needs, agencies do not duplicate each other's assessments, and professionals contribute to assessments in the most effective way" (Department of Health, 2002: p. 1). SSA models have been introduced elsewhere, for instance, the Australian Community Care Needs Assessment of 2007. However, there is greater emphasis on the importance of multidisciplinarity in the Australian model. While pioneers in favor of the development of a comprehensive assessment process promoted multidisciplinary and integrated assessments as faster and less costly (Øvretveit, 1993), the ongoing divisions between health and social care and chauvinistic protection of budgets derailed the smooth implementation of the process.

The original intentions indicated that local stakeholders, including older people, service users, carers, providers, other local statutory agencies such as housing, and local voluntary organizations should be involved in drawing plans for the local implementation of the SAP.

The Scottish Executive (2001) sought to implement SSA in Scotland by April 2002, echoing aims expressed by the English administration and building on guidance from the Scottish Joint Futures Group and community care guidance (SWSG 11/91, 1992; SWSG 10/98, 1998). The aim to reduce bureaucracy and to develop and work with shared protocols was again explicit. Assessment should be shared and led by one single professional, drafting in specialist involvement as appropriate. New legislation was not envisaged in Scotland for this process and the duty to assess under s. 12a of the Social Work (Scotland) Act 1968 remained.

The explicit principles on which the Scottish model was developed also demonstrated alignment with human service values. The model reflects an ideal and demands recognition of needs that set some of these principles in tension such as the development of a shared and agreed assessment tool that necessarily channels and limits the process; an implementation process facilitating joint working across health, social work, and housing; the development of minimum expectations and standards, which again are not overtly recognized as having sociopolitical, economic, and cultural elements attached. It is unlikely that a process could ever be developed that did not have such underpinnings but the necessity of bringing these to the surface and making them visible is something that was not undertaken, thus reducing the impact and effectiveness of reach of the SSA, and potentially leading to instrumental completion of assessments rather than the comprehensiveness desired.

When producing initial guidance on the SAP, the Department of Health in England was not envisaging radical change. Much of the required infrastructure was already in place within care management. In preparation for the implementation of the SAP in April 2004, nominal guidance, therefore, was issued (Department of Health, 2004) that principally reinforced and upheld earlier guidance providing a framework for a successful implementation. It was also emphasized that a key to a consistent approach was the way in which assessment information, subject to consent of the service user, was stored and shared, using the Single Assessment Summary or local equivalent as described in Annex I (Department of Health, 2002). This Annex was modified in November 2003. The need for appropriate training of professionals to enable them to carry out person-centered assessments and care planning (see Annex J, Department of Health, 2002) was reinforced and examples of good practice in the early implementation of the SAP were cited in a range of local authorities (Department of Health, 2004).

The UK government appeared confident that work on the SAP had been well developed and that initiatives were underway to build on this and develop a Common Assessment Framework 'to ensure less duplication across different agencies and allow people to self assess where possible' (Department of Health, 2006: p. 115). However, in practice, the SAP is still 'bedding in' and there has been a level of drift in its implementation that may be a reflection on the priority given to this process at national and local levels. Indeed, it was the government's intention that the implementation of SAP would be cost neutral and this has been met with a healthy skepticism (McNally et al., 2003). Anecdotal information indicates that practitioners are finding that the contact and overview assessments have a tendency to promote 'social work by numbers.' The forms are seen as extensive and health dominated and focus on a 'need to know' basis rather than a holistic assessment. The first professional person who visits the service user in his or her home is normally required to fill in the appropriate sections, but this does not always happen. Practitioners are wary of disclosing sensitive information on the service user (for example, financial information) that is usually left in a brightly colored

folder in a conspicuous place in the home. There is also the challenge created by professional differences and the meanings given to different terminology, for example, that of care planning (Parker and Bradley, 2010). Progress has also been hampered by the fact that not all organizations have a shared database and/or compatible electronic systems. On the other hand, local authority care managers can see the benefit of sharing assessments with allied professionals; in the old system the task normally fell to them and they were not always the best person to do this work.

Reflections on the Single Shared Assessment Process

From early days, research has exemplified continuing problems with implementing an SSA process (Glasby, 2004). Clare and Cox (2003) opine that the emphasis on inclusion, while laudably reflecting the increasing presence of the voices of those using human services may not extend as far as people with complex needs, who may well appear too difficult to involve meaningfully and therefore may remain excluded. Taylor (2003) further suggested that a shortfall in both nursing and social work practitioners limited the efficacy of the SSA/SAP in providing appropriate community care services that meet needs at all levels of complexity. It is perhaps to be expected that ideologically motivated models often driven by political aims do not work as well as assumed in complex human situations. Social workers must remain aware of the hidden agendas of neoliberalism that concern cost-effectiveness and efficiency but work through such assumed social goods as standardization, multidisciplinary approaches, joined-up foci, and reduced bureaucracy. A critically reflexive stance is important.

Challis et al. (2010), writing about England, reported on a 2005–06 survey concerning comprehensive assessment patterns and their prevalence, including multidisciplinary models. The survey suggested that comprehensive assessments relating to older people with complex needs are hampered by a lack of multidisciplinary experts, and that the intended outcomes of the SAP in England – to develop systematic multidisciplinary services – was not working, and, indeed, would not become effective without further policy directives.

Related to Challis et al. (2010) and Abendstern et al. (2011) explored the levels and nature of integrated or shared assessments across health and social care in England after the implementation of the SAP. She and her colleagues considered the premise that the provision of timely and effective services required health and social care agencies to work closely together in conducting assessments. Of those responding to the survey, a broad commitment to integrated assessment was found, but involvement in the SAP and its implementation was patchy. The survey of lead officers for the SAP boasted an 82% response rate ($n = 122$), with almost 72% being local authority personnel. While promoted as integrated multidisciplinary assessment processes, it was social workers who most frequently engaged as lead professional when conducting SSAs, followed by district nurses and occupational therapists. Key findings indicated that the majority of areas surveyed had agreements in place to support integrated assessments, but the use of SAP data appeared more useful for determining intermediate care and care management as opposed to access to health funded continuing care or mental health services. Research by Powell et al. (2007), concerning the views of older people experiencing the SAP, confirms the potential for identifying 'low-level' need, but not as effective where formal, complex care may be needed. The 26 older people interviewed by Powell et al. reported that the process does not assist when there are resource constraints, illustrating the tensions between identified needs and limited resources. They also highlighted the centrality of social relationships in respect of health and well-being, which extends to relationships between professionals.

A search of Web-based local government policies on single shared assessments shows the drive toward standardization as an unquestioned good; a desire for mimetic practices that suggest normative social work best meets people's needs. The policies developing do not necessarily reflect research-led and evidence-informed approaches but desire for legitimacy, not seeming out-of-step, or being open to challenge. The dangers inherent in this for social workers include being funneled into practices predicated on assumed 'evidence' and coercive structures (the policy guidance and legislative underpinnings) that require critique if social workers are to maintain their stand together with the marginalized and disenfranchised within and outside of society. From December 2008 to March 2009, Miller and Cameron (2011) undertook a comprehensive, although not systematic, review of interagency assessment, including 23 papers. Their review included earlier systematic reviews of evidence and literature reviews (Abenderstern et al., 2008; Challis et al., 2008). They found similar policy drivers and the introduction of eligibility criteria for services in the four administrations of the United Kingdom. They also found common difficulties in devising assessment documentation and balancing the need for free text with tick-box approaches, and a resulting lack of standardization in the process that makes comparison and evaluation problematic to undertake. However, their review also identified positive features of the SSA process in managing risks, reducing duplication, improving standards in practice and recording, joint working and communication, and involving service users.

Undertaking any social work assessment demands two core skills:

1. administration, and
2. human relationship or interpersonal skills (Coulshed and Orme, 2006).

Alongside demands for an ability to organize, systematize, and rationalize assessment knowledge, there is a concomitant need reflected within the SSA process for humane sensitivity and a valuing of the uniqueness of each individual involved. Whether this person-centered approach is realized depends on the integrity and approach of the social work, rather than the standardized approaches determined, although the levels of support and concern for social workers performing the assessments are also important to the outcome. SSA or the SAP represents an attempt to humanize social work and health care services but this cannot be achieved by and of

itself. Social workers have a role in developing a reflexive and questioning approach that itself aligns well with the assessment task, and at times must challenge the assumed yet unsubstantiated positives associated with SSA if state, organization, or professional needs appear to be privileged above the needs of those individuals and communities whom social workers serve.

International Law and Treaties

Mark W Janis, University of Connecticut, Hartford, CT, USA; and University of Oxford, Oxford, UK

Abstract

International law is the law generated by more than one state to regulate the international transactions of both states and private parties. It includes rules drawn from treaties, customary international law, general principles of law, natural law, and equity. It is applied in international diplomacy, international courts and arbitrations, and domestic courts and arbitral tribunals. Its fields include the laws of war and peace, the law of the sea, the laws of diplomatic practice, the law of treaties, the law of recognition and succession of states and governments, international trade and commerce, international human rights law, the law of international organizations, international environmental law, international business law, and international criminal law.

For thousands of years what we now call *international law and treaties* have provided legal rules and processes, generally generated by more than one state, to regulate the international transactions of both states and private parties. Modern *international law and treaties* are grounded in the Roman *jus gentium* as transformed by seventeenth-century Dutch theorist Hugo Grotius, who argued that the law of nations consisted both of positive law (in the explicit form of international agreement and the implicit form of international custom) and of natural law as drawn from reason, religion, and necessity. The field of *international law and treaties* is vast and growing. It includes traditional topics such as the laws of war, the law of the sea, the law of ambassadors and diplomacy, the law of treaties, the law of recognition and succession of states, and the law of trade and merchants. New topics include the law of international organizations, international human rights law, international business law, international tax law, international environmental law, and international criminal law. International legal rules are enforced not only by international courts and arbitration, but by domestic courts, and in diplomatic practice.

Definition

International law and treaties is a term that in English has at least three modern meanings: (1) legal rules and legal processes generated by more than one state; (2) legal rules and legal processes that concern interstate relations; and (3) legal rules and legal processes that regulate the international transactions of states and private parties.

Nature and History

Traces of what we now term *international law and treaties* are as old as written history. Evidence of compacts between states and rulers of states dates back at least 4000 years; they chronicle agreements about, inter alia, war and peace, foreign merchants, and ambassadors, all still lively topics of the discipline. It is safe to say that international law and treaties figure as necessary features of human society, regardless of any juristic definition, description, or argument.

The modern intellectual tradition relating to international law and treaties owes much to Roman law. The Roman term *jus gentium*, the law of nations, described legal rules pertaining generally to foreigners when specific foreign rules were unknown or in conflict. These were rules thought to be so basic that they were shared by all nations. Hence, like natural law, the law of nations was presumed to exist without positive expression in formal legislation. In Roman law, *jus gentium* ordinarily was employed in legal matters concerning private transactions, such as marriage, wills, and commerce.

Despite its origins in Roman private law, the law of nations was adopted by European jurists in early modern times to describe certain public legal relations. For example, in the sixteenth century, Spanish writers such as Suarez and Vitoria employed principles of *jus gentium* to argue that the Spanish Crown owed legal duties of basic humanitarian conduct to all peoples, even the indigenous peoples conquered by Spain in the Americas.

The often alleged 'father' of international law is Hugo Grotius (1583–1645), a Dutch jurist exiled to Paris following the suppression of the liberal party in the Netherlands. Already an accomplished diplomat, jurist, and theologian, Grotius devoted the remainder of his life to the cause of peace. In the midst of Europe's disastrous 30 Years War (1618–48), Grotius published the law of nations' most famous book, De Jure Belli Ac Pacis, to demonstrate that legal rules and processes defined and limited the sovereign rights and aggressions of otherwise bitterly divided Catholic and Protestant states and that such legal rules and processes even applied to relations between Christian and non-Christian states.

Grotius elaborated a legal theory that still serves as the foundation of modern international law. He argued that sovereign states were defined and bound by two kinds of legal rules drawn from the law of nations: positive law and natural law. The positive law of nations, expressed in treaties and custom, was made by the explicit and implicit agreement of sovereign states. The natural law of nations, expressed in the natural laws of reason and religion, was the result of necessary rules binding everyone, even rulers of states.

The first part of Grotius' theory of *jus gentium* was quickly married to emerging seventeenth-century political theory, like that of Hobbes, positing the idea of *sovereign* states. Grotius'

consensual theory of the law of nations helps explain why treaties, such as the Peace of Westphalia that terminated the 30 Years War in 1648, are legally binding: sovereign states have authority both to legislate rules internally for their own territory and to make rules externally for themselves through interstate agreement. Grotius' legal theory also explains why sovereign states should not interfere in the internal affairs of other sovereign states: a nation's sovereign authority must be limited so that the sovereign authority of other states is protected. Such international legal principles that weave sovereign states together and protect them from each other continue to guide international relations today.

In his age, Grotius' *jus gentium* excited many rulers, including Gustavus Adolphus of Sweden (who is said to have used Grotius' book as a pillow while campaigning on his many wars), as well as many universities. In Germany, The Netherlands, and England, professorial chairs in the new discipline of the law of nations were created, commencing an outpouring of scholarly works further describing and developing the discipline.

Not all students, of course, were pleased by their professors; one of the earliest pupils of the noted English law professor, William Blackstone, rebelled against what he was taught about the law of nations. In 1789, Jeremy Bentham (1748–1832) rejected the term the *law of nations* as professed by Blackstone; Bentham argued in *An Introduction to the Principles of Morals and Legislation* that the discipline should be renamed *international law*. Bentham's invented word, *international*, successfully passed from international law to denominate many other disciplines, for example, *international relations*, *international politics*, and *international economics*.

More or less inadvertently, Bentham changed not only a term but the very definition of the discipline. Grotius' and Blackstone's classical definition of the *law of nations* focuses on legal rules and processes generated by more than one state. Bentham's definition of *international law*, however, focuses on the subjects of the discipline; these Bentham said were states and states alone. The classic *jus gentium* regards individuals, as well as states, as its subjects, possessing legal rights and duties and accessing legal process. For the sake of theory, Bentham rejected individuals as proper subjects of *international law*.

A third definition of the discipline, along with a new term to describe it, was provided by the US jurist Philip Jessup, who in 1956 proposed replacing both the term the *law of nations* and the term *international law* with a new term, *transnational law*. Jessup defined the discipline of *transnational law* as encompassing any legal rule or process, municipal or international, that has to do with international transactions of any state, entity, or individual.

It may or may not make a difference how one defines the discipline. For example, a rule about delimitation of the continental shelf not only emerges from a multistate source, a treaty, *à la* Grotius' *law of nations*, but it also relates to interstate relations *à la* Bentham's *international law*, and deals with international transactions *à la* Jessup's *transnational law*. Hence, such a rule easily fits within the discipline as described by all three definitions. However, other times the different definitions lead to conflict. For example, if one believes, along with Bentham, that only states may be subjects of *international law*, then one cannot believe that individuals have international legal rights and duties. This means that they cannot be protected by international human rights law against abusive state action or be subject to international criminal law. A contrary position is usually taken by those who subscribe to the ordinary definitions of the *law of nations* and *transnational law*. Nowadays in practice, although the term *international law* is very popular, some of its exclusivities have been softened both by the classical tradition of the *law of nations* and by the modern sentiment expressed in *transnational law*.

Domain

The domain of *international law and treaties* is vast and growing. The discipline's classical fields, many hundreds of years old, include the *laws of war* (both about going to war, *jus ad bellum*, and about the proper conduct of war, *jus in bello*), the *law of the sea*, the *law of ambassadors and diplomacy*, the *law of treaties* (how treaties are made, interpreted, and implemented), the *law of the recognition and succession of states*, and the *law of merchants* (traditionally, *lex mercatoria* was part of the law of nations). More recently, new fields in the discipline have emerged, including the *law of international organizations and institutions*, *international human rights law*, *international trade law*, *international financial law*, the *international law of Antarctica*, the *law of outer space*, *international environmental law*, *international refugee and immigration law*, *international criminal law*, the *law of international arbitration*, *international tax law*, and the *international law of state responsibility*. The proliferation of fields in the discipline of international law is due in large measure to the increasing numbers and kinds of international relationships among states, peoples, corporations, and institutions, as well as to the inability of national law and regulation to adequately cope with such international transactions.

The Legislative and Enforcement Questions of International Law

To comprehend the fundamentals of modern international law, it is important to understand that two questions have always beset the discipline. First, how is it possible to authoritatively generate international legal rules? And second how is it possible to realistically enforce international law? In short, without an effective international political system, it seems at first glance that there is neither an authoritative way to make international law nor a realistic process to enforce it. These questions are answered in practice by remarkably effective systems of international legal rules and international legal process.

International Legal Rules

How are international legal rules authoritatively made? International lawyers often turn to Article 38 of the Statute of the International Court of Justice (the 'ICJ') to help describe the formation of international legal rules. Article 38 sets forth the rules available to the ICJ, the court of the United Nations, in deciding cases before it, albeit there are other kinds of

international legal rules as well. The three principal sorts of international legal rules available to the ICJ are rules drawn from explicit international agreements (mostly treaties), rules drawn from international custom, and rules drawn from general principles of law. These are sometimes described as formal sources of international law in that they are the sorts of rule-making that are acceptable in form as legitimate in international law (cf the *material sources* of international law which are the evidences that show the substance of a specific rule).

Rules drawn from international agreements include international legal rules set out in treaties, compacts, conventions, protocols, or whatever may be a written agreement between or among states governed by international law. Nowadays, there are tens of thousands of such instruments; their norms constitute the greatest number of international legal rules. These explicit international rules are comparable not only to statutes in municipal law (in that they establish rules for general conduct), but to domestic contracts (in that they can make ad hoc agreements based on party consent) and to constitutions (in that they can constitute international organizations). They can also be more or less aspirational. Treaty rules are the international legal rules that tend to be both least ambiguous and most clearly based on state consent. All other kinds of international legal rules are more troubled by problems both of ambiguity and of authority.

A second type of international legal rule is *customary international law*. Ordinarily, customary international law is perceived as based on the implicit agreement of states and is composed of two elements. First is a consistent pattern of state practice; this defines the rule. Second is a belief, an *opinio juris*, that compliant state behavior is based on a sense of binding legal obligation. In practice, the determination of a consistent pattern of state practice is almost always controversial and involves a subjective weighing of evidences from state practice proving and disproving the rule. *Opinio juris* is even more controversial: states rarely indicate that they are behaving in international relations in a certain way because they feel compelled to do so by a sense of international legal obligation. Rather, *opinio juris* is usually an evaluation added by a judge or a commentator as a description of state practice.

The third kind of legal rule prescribed by Article 38 of the ICJ Statute is *general principles of law*. These are legal principles generally shared by most or all legal systems. This concept is rather similar to the original Roman notion of *jus gentium*, that is, rules so basic that they are to be found everywhere. In modern practice, general principles of law are usually developed by jurists through a comparative law search. The method proceeds by examining diverse municipal legal systems. If a rule is found to be common to most or all of the municipal legal systems examined, then the rule is also presumed to exist as a general principle of law in international law.

Of the three formal sources of international law provided for in the ICJ Statute, treaty and custom are, more or less, consensual in nature. Even general principles of law can be seen to have a consensual aspect since it can be argued that if states already recognize a legal rule internally, they may be presumed to accept that self-same rule externally. Beyond the ICJ Statute, however, other formal sources of international legal rules exist without displaying such real or alleged consensual foundations.

Such nonconsensual rules may be seen as being no longer in the camp of positive law, but belonging to that of natural law. Indeed, natural law itself has long been an important formal source of international law. However, the term *natural law*, once so common, is nowadays rarely used in discussions of international law. Instead, newer equivalent terms have emerged. Key among these are *jus cogens* and *fundamental norm*, both expressing the natural law idea that some legal rules are so fundamental that they can be found everywhere and the idea that they trump any conflicting rule of positive law. *Jus cogens* or fundamental norms are often thought to include both the basic principles underpinning the international system, for example, *pacta sunt servanda* (agreements are binding) and the very notion of 'sovereignty,' as well as those basic principles protecting key human rights, for example, legal norms protecting individuals against genocide, slavery, and torture.

Another nonconsensual form of international law is *equity*. Sometimes viewed as a corrective of the strict application of a legal rule (equity *contra legem*), equity can also involve rule creation (equity *praeter legem*) and rule interpretation (equity *infra legem*). Equitable rules or principles can be based on nonlegal criteria, such as distributive justice and basic notions of fairness.

International Legal Process

How are international legal rules enforced in practice? Most times when international legal rules are recognized, they are applied by the nation states themselves. So, for example, all kinds of international legal rules, whether they be drawn from treaties, custom, general principles of law, *jus cogens*, or equity, are applied from time to time by municipal courts. Approaches to this process usually are thought to be either *dualistic* or *monistic*. *Dualism*, the prevalent view, holds that municipal legal systems and international legal systems are distinct from each other (dualist) and that there need to be rules of *incorporation* providing why, when, and how a rule of international law is to be applied by a municipal court. *Monism*, the less usual view, sees both international law and municipal law as parts of a unified system of law, where incorporation of international legal rules into municipal law is to be presumed.

Different municipal legal systems have different answers to questions of the incorporation of international law. Moreover, a municipal legal system's rules about incorporation may vary depending on the type of international legal rule concerned. So, for example, though treaty rules are sometimes deemed to be *self-executing* in the United States, that is, requiring no domestic legislation to put them into internal effect, in Great Britain treaty rules are never self-executing: all require an act of Parliament before they can be employed as rules of decisions by municipal courts. However, respecting customary international law, the United States and Great Britain share a similar approach. Both municipal legal systems deem some sorts of customary international law to be part of the *law of the land*, available to municipal courts without legislative act.

Besides providing rules of decision for municipal courts which then enforce the international rules alongside municipal law, international law is also enforced by procedures in the international legal system. There are, for example, an increasing

number of international courts. Oldest among these is the International Court of Justice at The Hague, which dates its antecedents to the Permanent Court of Arbitration established by The Hague Peace Conference of 1899, and to the Permanent Court of International Justice, established under the auspices of the League of Nations in 1921. The International Court of Justice was established alongside the United Nations, its parent institution, in 1945. The Court is composed of 15 judges elected by the UN General Assembly. There are usually ICJ judges from China, France, Russia, the United Kingdom, and the United States.

Reference has already been made to the ICJ Statute, the treaty that authorized the creation of the Court. The ICJ Statute also provides for two kinds of jurisdiction for the Court. First is its *contentious jurisdiction*; here the Court, with the prior consent of the parties to the dispute, actually decides cases between states. However, neither international organizations nor individuals may be party to the ICJ's contentious jurisdiction. The second sort of ICJ jurisdiction is its advisory jurisdiction: at the request of some international organizations (though neither states nor individuals), the ICJ may render a legally nonbinding advisory opinion on a legal matter. Since 1921, the practice of the Permanent Court of International Justice and the International Court of Justice has remained roughly steady: about three or four judgments or advisory opinions rendered each year.

Since 1950, a great many new international courts have been created. Each of these courts is limited either geographically or by its subject matter, but some have become a great deal busier than the older and more universal ICJ. Europe's two regional courts – the European Court of Human Rights in Strasbourg (established by the European Convention of Human Rights in 1953 and comprising 47 member countries) and the European Court of Justice in Luxembourg (the highest court of the European Union) – nowadays decide hundreds of cases each year. Less busy but still important are international courts and international dispute-settlement procedures such as the Law of the Sea Tribunal in Hamburg, the World Bank's International Center for the Settlement of Investment Disputes in Washington, the Inter-American Court of Human Rights in Costa Rica, the World Trade Organizations' dispute-settlement procedures in Geneva, the international criminal tribunals for the former Yugoslavia in The Hague and for Rwanda in Kenya, and the International Criminal Court in The Hague. Unlike the states-only provisions limiting the ICJ, all these newer international tribunals permit individuals in some circumstances to be parties to litigation.

In addition to the increasing number of international courts, there are a great many international arbitral procedures available to provide ad hoc jurisdiction to settle international legal disputes, public and private. Many of these international arbitrations are organized under the auspices of one of the international arbitral institutes. Two of the busiest are the International Chamber of Commerce in Paris and the American Arbitration Association in New York.

Finally, international law is often enforced simply by the diplomatic practice of governments. Reciprocity and good faith, outside any formal dispute settlement procedures, account for the lion's share of cases in which international law is effectively employed. It would be difficult for much of the world's business, public and private, to get done unless governments followed similar practices set out in treaties, custom, and the other kinds of international law.

Prognosis

It is likely that international law and treaties, already employing tens of thousands of international lawyers worldwide, will continue to prosper and expand. Modern trade, communications, and transportation have all been globalized much more thoroughly than modern politics, which remains largely state-centered. It is likely that without a political or social impetus for internationalization of political decision making, the sovereign state will remain the principal vehicle of government. Accordingly, international law and treaties will shoulder the burden of harmonizing and facilitating the growing number of transactions among the world's nations.

Abstract

Immigration is on the rise in recent decades. In this article, we first provide an overview of the recent evolution of global migration flows. We then analyze the main drivers of international migration, and how they have changed over time. Finally, we review the theoretical and empirical findings of the growing literature that analyzes the economic consequences of immigration in destination countries.

Introduction

Migration is an old phenomenon. Population movements have characterized the history of mankind but the size of the international migrant stock, both in absolute terms and relative to the world population, has never been higher. In 2013, 231 million people (3.2% of the world population) live in a country, which is different from where they were born, up from 75 million (2.3%) in 1965. These numbers indicate that migration is becoming increasingly relevant, although it has been influentially argued (see for instance Pritchett, 2006) that labor mobility is still 'too low' compared to the mobility of capital and goods.

In this article, we first provide a systematic assessment of the main facts and trends that characterize recent international migration flows. We then examine the most important migration drivers identified in the literature, and discuss their evolution over time. Finally, we review the main findings about the economic consequences of migration in receiving countries.

The Changing Geography of Migration

The period after World War II has seen significant changes in the main group of destination countries of international migration flows. **Figure 1** shows the worldwide distribution of the stock of immigrants in 1960. Darker shaded areas indicate locations that have been more intensively exposed to the phenomenon. As is immediately clear, in 1960, immigration was particularly important for countries in Oceania like Australia and New Zealand, and for North American destinations like Canada. Argentina also was characterized by a large number of foreign-born, representing 12.6% of the total population. On the other hand, during this period, the stock of foreign-born in the United States reached a historic low, as a result of the restrictive policies introduced in the aftermath of World War I (see Goldin, 1994), which were removed only in 1965. Importantly, immigration was sizable also in a variety of other destinations, particularly in the developing world.

During the boom years of the 1960s, immigration took off on a global scale. In the United States, the 1965 reform led to a radical change in the channels of entry of new immigrants, with family reunification taking a leading role. The result was large inflows from Latin American countries, and Mexico in particular, that substantially reshaped the ethnic composition of the US population. During this period, the other major North American destination country, Canada, continued to pursue a relatively open immigration policy stance but, in 1967, it introduced the so-called 'point-based system,' a pioneering approach to select immigrants based on observable individual characteristics. Australia and New Zealand continued their efforts to populate their vast territories, promoting in particular the arrival of 'white' immigrants. As for Europe, traditional destinations continued to actively recruit foreign workers throughout the 1960s and the early 1970s. The oil crisis of 1973 represented a critical turning point, since most countries suspended or withdrew from the bilateral workers recruitment agreements they had signed during the boom years. While this policy change had a clear impact in the short run, leading to a substantial decline in new inflows, it made also apparent the limitations of the temporary immigration programs. In fact, only very few of the temporary migrants who in the 1960s arrived in Northern European countries ended up returning home in the 1970s.

Throughout the 1970s and the 1980s, immigration flows started to pick up in the United States and Canada (average annual inflows to the United States during the 1980s reached almost 650 000 and to Canada 126 000; source: OECD International Migration Database) and in Australia and New Zealand. At the same time, the number of foreigners residing in European countries was broadly stable (Dustmann and Frattini, 2013) and started to increase only during the late 1980s, as a result of the better conditions prevailing in the local labor markets.

Figure 2 captures the distribution of international migrants in 2013. At the global level, several important changes have occurred compared to 1960. First, Australia, Canada, and New Zealand have become increasingly reliant upon foreign workers throughout this period and in fact, in 2013, well over 20% of their population was made up by foreign-born individuals. This development has been the result of immigration policies that have allowed large inflows of foreign workers and

Figure 1 Migrant stock as % of total population, 1960. Source: Our elaboration on United Nations Population Division, Trends in Total Migrant Stock: 2008 Revision.

Figure 2 Migrant stock as % of total population, 2013. Source: Our elaboration on United Nations, Department of Economic and Social Affairs (2013). Trends in International Migrant Stock: The 2013 revision.

increasingly focused on skilled migrants, in particular after 1985. At the same time, large inflows of immigrants throughout the 1990s and the following decade have made the foreign-born population in the United States reach levels not seen since the end of the great migration of the early twentieth century. In fact, by 2013, slightly more than 14% of the US population was born abroad (i.e., a total of 45 million individuals).

Second, oil-rich countries in the Persian Gulf area, but also elsewhere like Gabon and Libya, have emerged as the host of very large numbers of foreign-born individuals. While these inflows were the result of skill shortages – of engineers and oil-field workers as well as of financial professionals and service-sector workers – the integration of foreigners in the local societies has been the source of much concern both among source country governments and international organizations (see Ruhs, 2013). Compared to 1960, it is also important to point out how some areas of the world have become less attractive destinations for foreign workers. This is, in particular, the case of Latin America, where over the period 1960–90, the migration inflow came to a complete stop. Some Latin American countries actually turned into positive net *emigration* countries.

The fall of the Berlin wall and a rapidly growing economy during the 1990s have also contributed to substantially change the geography of migration in Europe. By 2013, traditional Northern European destinations harbored large numbers of foreigners, often representing well in excess of 10% of the total population. At the same time, Southern European countries, which in the 1950s and 1960s had been the source of large outflows of workers, have now turned into the destination of large migration inflows. In 2013, 13.8% of the Spanish population is foreign-born and a large immigrant population is also harbored by Italy.

The Drivers of International Migration

A growing literature (see e.g., Mayda, 2010; Ortega and Peri, 2013) has investigated – using aggregate data – the determinants of international migration flows, identifying a series of factors that play a key role. These can be summarized as follows:

- Average income differentials between the home and destination countries
- The distribution of income in the source and the destination countries
- Geographic and cultural distance
- Immigration networks
- Immigration policies

In what follows, we will review the role of each of these determinants.

Average Income Differentials

At least since Sjaastad's (1962) pioneering contribution, economists have modeled the decision to migrate as the result of an income maximization choice, where different locations offer different opportunities. Earlier contributions have focused on bilateral differences, while more recent analyses (Bertoli and Fernandez Huertas Moraga, 2013) have explicitly considered the choice among several alternative locations. Estimates in the literature show that international migration flows are highly responsive to per capita GDP in the destination country. This is consistent with **Figure 3**, where the share of international migrants in the host country's population is positively and significantly correlated with destination country's per capita GDP. The evidence in the literature on the impact of origin country's per capita GDP is instead more mixed.

The Distribution of Income in Source and Destination Countries

While average income differentials are key drivers of the migration decision, workers differ along multiple dimensions and the literature has emphasized the role that individual characteristics are likely to play. An important framework to understand the selection of immigrants along observable features – with respect to both the population in the origin and destination countries – has been proposed by Borjas (1987). The basic idea of his model is that – under specific assumptions on the structure of the migration costs – the relative dispersion of income in the source and the destination countries is a key determinant of the characteristics of who will migrate. Two scenarios are particularly relevant. In the first one, known in the literature as 'positive hierarchical sorting,' migrants are positively selected both at the source and the destination. This is likely to occur when the return to skills in the destination country is higher than in the country of origin and the correlation between the return to skill in the two countries is sufficiently high. This is a desirable situation from the point of view of the host country, as immigrants represent the 'best and the brightest.' An alternative scenario, known as 'negative hierarchical sorting' implies instead a situation in which immigrants are negatively selected both at the source and the destination. This scenario is likely to occur when the return to skills is higher in the source than in the destination country. This is a less desirable outcome from the point of view of the destination, as in this case migrants would tend to be overwhelmingly low-skilled workers.

Figure 3 GDP per capita and immigrant share. Source: Our elaboration based on data from the World Bank.

Several macro papers have pointed out the relevance of inequality in the source and the destination countries in explaining immigration flows. A recent historical study (Abramitzky et al., 2012), based on a particularly rich data set of Norwegian families at the end of the nineteenth century, provides instead detailed microlevel evidence in an environment where the predictions of the model can be tested more systematically. In particular, in this article, the authors are able to compare brothers who emigrated to the United Sates, with brothers who instead remained in Norway, supplying very clean evidence in favor of Borjas' (1987) model.

Geographic and Cultural Distance

The third channel that has been emphasized by the literature concerns immigration costs and how they shape the economic calculus of foreign workers when deciding where to settle. We start by looking at the cost of moving abroad – e.g., transportation costs – and we then turn to proxies for other migration costs, e.g., the cultural distance between the source and the destination country's society.

Figure 4 uses data from the UK Department of Transportation to calculate the real price of an average international airfare during the post-1970 period. As we can see, there has been a rapid and sustained decline in the costs of moving from one country to another, on average involving a reduction of 49.7% in the case of business travel, and an even more remarkable decline of 69.1% when it comes to leisure flights.

Measuring the evolution of cultural distance across countries is a much more complex endeavor, but we can consider at least two proxies that provide useful information to that end. First, Figure 5 reports information on the dynamics of communication costs for a group of six European countries.

Figure 4 Average fares on international flights. Source: Our calculations based on data from the UK Department of Transportation and the National Archives.

Figure 5 International phone call rates. Source: Our elaboration on Eurostat data.

The data, taken from Eurostat, provide a picture of the rapid decline in the cost of international phone calls, both in immigrant destination and source countries.

Our second proxy for the evolution of cultural distance concerns the diffusion of the Internet. The idea is that as a larger share of the population gains access to the World Wide Web, individuals become more exposed to the value systems prevailing in other countries, and are thus better informed concerning the characteristics of possible destinations before relocating there. Figures 6 and 7, comparing the situation in 1995 and 2012, show that, while a clear digital divide continues to persist between the South and the North of the world, the Internet access has grown exponentially in many developing countries. This has led to a dramatic reduction in the uncertainty faced by individuals in their decision. Economic theory suggests that, everything else equal, this will increase migrants' probability to move.

Immigrant Networks

The fourth determinant of immigration flows that has been emphasized by the literature is the so-called network channel. The basic stylized fact is that migrants (especially from the same origin country) tend to cluster in specific areas (see e.g., Munshi, 2003). This is particularly true for less-skilled individuals and for new arrivals. This last point is nicely illustrated for the United States in a paper by Scott et al. (2005), who establish a strong positive relationship between the existing stock of immigrants in a metropolitan area in 1990 and the immigration flow between 1990 and 1998. The particularly striking result is that six US cities account for approximately 70% of the total settlement of new immigrants, suggesting that preexisting immigrant communities do play a very important role in attracting new arrivals.

But why do migrants tend to cluster together? Several explanations have been put forward in the literature, and the

Figure 6 Internet users per 100 inhabitants, 1995. Source: Our elaboration on World Bank, World Development Indicators data.

Figure 7 Internet users per 100 inhabitants, 2012. Source: Our elaboration on World Bank, World Development Indicators data.

basic idea is that immigrant networks tend to reduce the cost of migrating (Munshi, 2003).

Immigration Policies

As argued by several observers, the gap in living conditions between the North and the South of the world is so large that the unencumbered flow of workers would allow the global economy to reap huge efficiency gains. Restrictions have made these gains hard to obtain and, in particular, a key role has been played by the policies adopted by destination countries. A few studies have investigated the views of the different actors that play a key role in shaping immigration policy in the destination countries. In particular, Facchini and Mayda (2008) have looked at individual voters' attitudes toward immigration, whereas Facchini and Mayda (2010) have studied the views of key officials in the government. Both suggest that – at least for the near future – it is not realistic to expect large changes in the policy stance, as both public opinion and government officials are not in favor of substantially liberalizing existing policies.

The Impact of International Migration Flows on Destination Countries

International migration affects the destination country's economy through a variety of channels. In this section, we review the main ones, first highlighting the theoretical mechanisms at work and then briefly discussing the most recent empirical findings.

Labor-Market Effects

Assume that skilled and unskilled labors are combined to produce a single good according to a constant returns to scale production function. In this model, immigration inflows increase the labor supply in the destination economy, thus generating a *surplus* with respect to the premigration situation. Importantly, this surplus will not be evenly distributed among the residents of the host country. The income-distribution effects of migration depend on the skill composition of migrants relative to natives. If immigrants are, on average, less skilled than natives, skilled workers will benefit from migration, while unskilled workers will be on the losing end. The reason is that the arrival of immigrants will give rise to a decrease in the unskilled wage and an increase in the skilled wage. If, on the other hand, immigrants are, on average, more skilled than natives, the income-distribution effects of migration are reversed, i.e., immigrants will hurt skilled natives and benefit unskilled ones, as their arrival will induce a decrease in the skilled wage and an increase in the unskilled wage (see Borjas, 1995).

Of course, these predictions rely on the assumption that similarly skilled natives and immigrants are perfect substitutes in production. This assumption might not be very realistic: migrants might lack some country-specific dimension of human capital (like language) and thus cannot compete with native workers with the same level of formal skills. Two recent studies have analyzed the substitutability of immigrants and natives in the UK (Manacorda et al., 2012) and the US (Ottaviano and Peri, 2012). Both studies find that immigrants are not perfect substitutes for natives, even within narrowly defined skill groups, but partly complement their skills. In particular, these studies show that once imperfect substitutability within skill groups is taken into account, the group most negatively affected by new immigrant inflows is that of previous immigrants. One of the reasons of the imperfect substitutability between native and immigrant workers is that these two types of workers tend to specialize in different tasks. In fact, it has been shown (Peri and Sparber, 2009) that unskilled immigrants to the United States have specialized in occupations requiring manual and physical skills, while unskilled natives are employed in language-intensive occupations. Interestingly, a similar pattern of specialization is at work among skilled workers (Peri and Sparber, 2011). To conclude, while these considerations suggest caution in defining skill levels based on educational qualifications, the basic idea underlining the models of perfectly competitive labor markets still remains valid, once care is taken in appropriately defining skill groups (see for instance Dustmann et al. (2013), where skills are defined in terms of position in the wage distribution).

Note that, if immigration affects factor prices, it will also affect the production cost of goods and services. Assuming that output markets are sufficiently competitive, changes in production costs should be reflected in output prices. This channel will operate especially for nontradable goods and services, whose prices are set locally, whereas it is less likely to be at work in the case of tradable goods, as their prices are set on international markets. Does this change in production costs pass through to consumers? Some studies suggest that this is indeed the case (e.g., Cortes, 2008). In particular, immigration has been shown to reduce price growth in low-wage and immigrant-intensive service sectors, with the strongest effects being concentrated in those sectors that use more intensively low-wage workers.

Effects on Output Mix and on Production Techniques

In recent years, researchers are paying increasing attention to other channels – beyond changes in factor and output prices – through which the economy absorbs migration flows. One widely studied mechanism is represented by changes in the output mix. Consider a stylized economy characterized by two factors, skilled and unskilled labor, and two sectors which are, respectively, skilled- and unskilled-labor intensive. In this case, as long as the destination country is a small open economy, it is diversified in production and the size of the migration stock is small, an inflow of unskilled migrants will increase (decrease) the production of the unskilled-labor-intensive (skilled-labor-intensive) good while leaving wages unaffected.

A further adjustment might take place through changes in the production techniques used by firms. In other words, if, for example, an inflow of unskilled migrants takes place, firms can adjust to the changes in relative labor supplies by adopting technologies that use more intensively unskilled labor. There is evidence that immigration has affected the choice of techniques of production in the United States. Even within the same narrowly defined industrial sector, firms in metropolitan areas that have received more unskilled immigrants have decreased their use of automation equipment and have

consequently decreased their equipment-output ratio (Lewis, 2011). Similarly, it has been convincingly shown that in areas with a relatively large immigration-induced increase in the skilled workforce, the adoption of personal computers between 1990 and 2000 took place more rapidly than in areas receiving less-skilled immigrants (Doms and Lewis, 2006). What about changes in output mix? Hanson and Slaughter (2002) find evidence of immigration-related changes in output mix in US states. Some studies have explicitly analyzed the relative importance of changes in techniques of production as compared to changes in output mix in explaining how economies adjust to immigration (see Lewis (2013) for a comprehensive survey of this literature). The results are remarkably robust and suggest that economies adjust to immigration-induced changes in skill mix mostly via within-industry changes in skill intensity; conversely, changes in output composition account for only a small fraction (typically around 10%) of the adjustment.

Productivity and Innovation Effects

One related important issue, which has only recently been studied, is the contribution of immigrants to productivity growth and innovation in the host country. The effects on total factor productivity (TFP) may arise for several reasons. For example, immigration gives rise to changes in the skill composition of the workforce, which affect the probability of innovation. In particular, high-skilled immigrants might benefit the host country via 'human capital spillovers' (see e.g., Moretti, 2004). In addition, immigrants display systematic differences in cultural background, risk attitudes, and language skills compared to the destination country population, etc.

It has been shown, for instance, that labor productivity increased more slowly in the US states that attracted a larger share of immigrants during the 1980s, both in low- and high-skill industries, which suggests that the effect is not due to the low-skill levels of immigrants, but rather to their imperfect short-run assimilation in the US economy (see Quispe-Agnoli and Zavodny, 2002). However, the negative effect on productivity growth may disappear as immigrants acquire language skills and familiarity with the labor market institutions of the host country. Indeed, analyses of the long-run effects of immigration on TFP have shown that, over the period 1960–2006, immigration exerted a strong positive effect on TFP in the United States (see Peri, 2012).

Finally, Hunt and Gauthier-Loiselle (2010) investigate the impact of immigration on innovation and find a positive relationship between the number of patents per capita and skilled immigration at the state level. Kerr and Lincoln (2010) show evidence of a positive effect of the number of H1B visas granted on the direct contribution of ethnic innovators. These papers find that skilled immigrants in the US patent at twice the native rate. In addition, the higher patenting rate of immigrants has not crowded out natives' patenting. On the contrary, there are positive spillovers of immigration on a state's innovation activity: a 1% point increase in the share of immigrant college graduates in the population increases patents per capita by 9–18%. Immigration seems to have boosted innovation in Europe, too. A recent study on 20 European countries (Bosetti et al., 2012) has demonstrated that skilled immigration has led to higher levels of knowledge creation, measured either by the number of patents or by the number of citations to published articles.

Welfare-State Effects

The main OECD destination countries of immigrant flows are characterized by large welfare states (Boeri et al., 2002), through which the public sector redistributes a substantial fraction of national income across individuals. In these contexts, immigration has a nonnegligible impact on public finances, since foreign workers both contribute to and benefit from the welfare state. The aggregate net effect of immigration on the welfare state is either positive or negative, depending on the socioeconomic characteristics of immigrants relative to natives. If immigration is skilled, natives are likely to benefit from the presence of foreign workers, due to a positive welfare spillover. On the other hand, if migration is unskilled, natives may be negatively affected, through a welfare-state leakage effect. Besides this aggregate effect, through the welfare-state channel, immigrants also give rise to income-distribution effects (see Facchini and Mayda, 2009). Consider a simple redistributive system, in which all income sources are taxed at the same rate and all individuals in the economy, i.e., both natives and immigrants, are entitled to an equal lump sum per capita benefit. By construction, this simple welfare system redistributes resources from high- to low-income individuals. Thus, the extent to which natives are affected by migration through the welfare-state channel differs according to each voter's income level. That is, there will be income-distribution effects. These effects depend on the adjustment mechanism of the welfare state to migration. On the one hand, migration can bring about changes in the tax rate, while per capita benefits are kept constant (*tax adjustment model*). On the other, the per capita benefits can adjust, while tax rates are unchanged (*benefit adjustment model*).

Under the tax adjustment model, if immigration is skilled compared to the native population, all individuals benefit from the inflow of foreign workers, since the government will be able to lower the tax rate (while keeping the level of per capita benefits unchanged). However, the reduction in the tax rate will benefit rich individuals to a greater extent than poor ones, since tax payments represent a larger fraction of rich voters' net income. If immigration is on the other hand unskilled, all individuals are worse off, since the tax rate needs to increase to keep the level of per capita benefits unchanged. Richer individuals are those more negatively affected, since the burden of financing the welfare state falls disproportionately more on richer members of society. To summarize, under the tax adjustment model, any change in tax rates (either negative or positive, depending on the skill mix of migrants) will have a bigger impact on high-income individuals.

As in the tax adjustment model, also under the benefit adjustment model, an inflow of skilled immigrants benefits all individuals, while an inflow of unskilled immigrants worsens the position of all natives. The difference is that, under the benefit adjustment model, an inflow of immigrants will have a more pronounced effect (either positive or negative, depending on the skill mix of migrants) on those individuals who are at the receiving end of the welfare system, i.e., those

with a low income. The reason is that the per capita benefit represents a larger fraction of a poor individual's net income, thus changes in per capita benefits affect this group more strongly. In particular, if a country receives skilled migrants, the per capita benefit will increase, and all natives will be made better off, but poor ones more so than rich ones. On the other hand, a country receiving unskilled migrants will be forced to reduce per capita benefits, thus hurting everybody, but again low-income voters to a greater extent than high-income ones.

Conclusions

In this article, we have systematically assessed the main facts and trends that characterize recent international migration flows and have provided a short review of the research on the causes and consequences of migration. Space constraints have forced us to focus only on the effects of immigration on destination countries. However, it is important to keep in mind that immigration significantly affects source countries too, especially through large remittance flows, and through its impact on the availability of human capital.

It is not an overstatement to say that international migration could radically change the future of the world economy in the next decades (as has happened with trade in goods and services and capital flows). The drop in transport costs and cultural distances in modern economies, coupled with persistent income differentials across countries, have led to an unprecedented increase in migration pressures. A clear understanding of the determinants and impacts of this phenomenon is the starting point of sound economic policies, both in destination and origin countries.

Abstract

The remittances that these migrants send to origin countries are one of the largest types of international financial flows to developing countries. This article reviews the relationships between remittances and the economic development of the world's poorer nations. It first reviews the definition, magnitude, and some basic characteristics of remittance flows. Then, it treats the motivations for remittances, the impacts of remittances on development outcomes, and their role in helping respond to adverse shocks. It concludes with thoughts about the immediate future of remittances and promising areas for future research on the topic.

Between 1965 and 2000, individuals living outside their countries of birth grew from 2.2 to 3.1% of world population, reaching a total of 214 million people in 2010 (United Nations, 2011). The remittances that these migrants send to origin countries are one of the largest types of international financial flows to developing countries.

This article is on remittances and their relationship with the economic development of the world's poorer nations. It will first review the definition, magnitude, and some basic characteristics of remittance flows. Then, it will treat the motivations for remittances, the impacts of remittances on development outcomes, and their role in helping origin countries and – households respond to adverse shocks. It will conclude with thoughts about the immediate future of remittances and promising areas for future research on the topic.

Definition, Magnitude, and Basic Characteristics

Remittances are household income received from overseas, primarily initiated by international migrants sending funds to home countries. Remittances may be sent as cash or in kind, and may flow through a variety of formal or informal channels. Formal channels include dedicated money transfer operators (e.g., Western Union, MoneyGram), banks, and credit unions. Informal channels include systems – such as *hawala* and *hundi* in South Asia and *padala* in the Philippines – operated by nonfinancial firms or brokers. In international balance of payments data, remittances are measured as the sum of two categories of transactions: 'personal transfers' (all current transfers in cash or in kind made or received by resident households to or from nonresident households) and 'compensation of employees' (earnings of temporary workers who are not resident in their host countries) (International Monetary Fund, 2013).

Since the late 1990s, remittances sent home by international migrants have exceeded official development assistance, and in several years have approached the magnitudes of foreign direct investment (FDI) flows. Figure 1 graphs these four categories of financial flows to developing countries from 1991 to 2011. In 2011, migrant remittances sent to developing countries amounted to US$353 billion. Developing country receipts of

Figure 1 Remittances vs other international financial flows to developing countries (1990–2011). Note: Data are from the World Bank's World Development Indicators (WDI) 2013. Data are in billions of constant (2005) US$, in total across developing countries (low and middle income as classified by World Bank). Variables displayed are 'net official development assistance and official aid received (current US$),' 'foreign direct investment, net inflows (BoP, current US$),' and 'personal remittances, received (current US$).'

Table 1 Top remittance recipient countries

	Remittance receipts (USD billions), 2013 estimate		*Remittances received as % of GDP, 2012*
India	71	Tajikistan	48
China	60	Kyrgyz Republic	31
Philippines	26	Nepal	25
Mexico	22	Lesotho	25
Nigeria	21	Moldova	24
Egypt	20	Armenia	21
Bangladesh	15	Haiti	21
Pakistan	15	Samoa	21
Vietnam	11	Liberia	20
Ukraine	9	Lebanon	17

Note: Data on the dollar value of remittances received are estimated for 2013, and data on remittances received as share of GDP are from 2012. For estimation methodology, see Ratha, Dilip, Eigen-Zucchi, Christian, Plaza, Sonia, Wyss, Hanspeter, Yi, Soonhwa, 2 October 2013. Migration and Remittance Flows: Recent Trends and Outlook, 2013–2016. Migration and Development Brief 21. Development Prospects Group, World Bank.

FDI (the largest type of international financial flow to the developing world) were less than double that figure ($646 billion). Receipts of official development assistance (foreign aid) came in a poor third to remittances and FDI in 2011, amounting to just $141 billion. (Data are from the World Bank's World Development Indicators 2013. The 2008–09 financial crisis had a substantial negative impact on FDI flows, while remittances and ODA were by contrast relatively stable. In 2009, FDI, remittance, and ODA flows to developing countries were $382, $282, and $126 billion, respectively.) The World Bank estimates that remittances to developing countries will amount to $414 billion in 2013 (Ratha et al., 2013). Motivated by their large magnitudes, international financial institutions and developing country governments are keenly interested in finding policies that can stimulate remittances and enhance their development impacts.

Table 1 displays remittance data for the 10 largest remittance-receiving countries, ranked by dollar value (column 1) and by share of GDP (column 2). The largest remittance-receiving countries in 2013 by (estimated) dollar value are India and China, which received $71 billion and $60 billion, respectively. The Philippines and Mexico are nearly tied for the next two places, receiving $26 billion and $22 billion, respectively. When it comes to remittances as a share of GDP, on the other hand, rankings (based on 2012 data) are very different. Countries with small populations but large migrant flows end up at the top of this list, led by Tajikistan (where remittances amount to 48% of GDP) and followed by the Kyrgyz Republic (31%), Nepal (25%), Lesotho (25%), and Moldova (24%).

Remittances are not only large in aggregate magnitude. They are also prominent in the context of individual financial lives, making up a substantial fraction of migrant workers' earnings. Table 2 presents data on remittances sent as a fraction of earnings from several surveys of various migrant populations. For many migrant populations, the share of earnings remitted is substantial. Mexican migrants (surveyed upon return to Mexico) remit 31.1% of earnings, while migrants from El Salvador surveyed in the Washington, DC, area in 2007–2008 report remitting 37.7% of their United States earnings. Senegalese in Spain remit 49.9% of earnings, and Ghanaians in Italy 23.3%. In other surveyed migrant populations, the share of remittances out of earnings is more modest: Moroccan immigrants in France remit 10.4% of earnings, Turks in Germany 2.1%, Chinese in Australia 6.1%, Filipinos in the United States 5.8%, and Cubans in the United States 2.3%.

Remittances differ from the other large types of international financial flows to developing countries – such as FDI and official development flows – in that they are sent at relatively high frequencies and in relatively small magnitudes. This pattern has been found in a diverse variety of migrant populations.

For example, Yang (2011) analyzes transaction-level data from a money transmitter in Washington, DC, and finds that

Table 2 Remittance activity in selected migrant origin-destination country pairs

Origin country	*Migrant destination country*	*Average remittances as a percentage of earnings (%)*	*Average annual remittances ($ value)*	*Data source*	*N*

Cuba–United States: Pew National Survey of Latinos (US Pew), http://pewhispanic.org/datasets/signup.php?DatasetID=7.

migrants from El Salvador sent an average of 16.9 remittances over a 12-month period in 2006–2007, with more than a fifth of migrants undertaking 26 or more remittance transactions (at least biweekly) over the period. The average amount sent per remittance was $299.21, and the median was $200. In 88.6% of transactions, the amount sent was $500 or less. These patterns are consistent with other surveys of Hispanic immigrants in the United States. Orozco and Fedewa (2006) report that 81% of individual remittance transactions sent to a major bank in Guatemala were equal to or less than $300. Bendixen and Associates (2008), in a survey of 5000 Hispanics in the United States, found that 50% sent remittances on a regular basis, remitters sent on average 15 remittances per year, and the average amount sent per remittance was $325. Other survey-based studies finding similar results include Menjivar et al. (1998), DeSipio (2000), Clark and Drinkwater (2001), Bendixen and Associates (2001, 2004a,b), and Amuedo-Dorantes et al. (2005).

Motivations Behind Remittances

The motivations for remittances are varied, and often overlap with motivations behind the original decision to migrate. Migration is frequently well-described as an investment on the part of the migrant and his or her family, where the returns to the investment take the form of higher earnings in a more developed migration destination. In this context, remittances often constitute the portion of the investment return from migration that accrues to individuals in the migrant origin country (Clemens and Ogden, 2013; De Haas, 2010). Docquier and Rapoport (2006) provide a model of the remittance-sending decision that incorporates a variety of motives, including altruism, exchange (compensation for services rendered to the migrant by recipients), insurance, loan repayment, and investment, some or all of which could operate simultaneously.

Altruistically motivated migrants could send remittances to increase recipient consumption levels (Stark, 1995), and may also be responsive to shocks experienced by recipients and thus play an insurance function (Cox et al., 1998; Gubert, 2002). Remittances may be intended for physical or human capital investments by recipients. Remittances could also have self-interested motivations, such as repayment of debts incurred for the migrant's education in the home country or the initial fixed costs of migration (Poirine, 1997; Ilahi and Jafarey, 1999). Remittances could also be intended for migrants' future investments in the home country, or for monitoring or administration of investment assets. Remittances may be sent to secure a future inheritance from elders being supported in the home country (Hoddinott, 1994; de la Briere et al., 2002; Osili, 2004).

Impacts of Remittances

Remittances have a variety of impacts on recipient countries and households. Aggregate analyses of the relationship between remittances and economic performance at the country level are inconclusive. Some studies find a positive relationship between remittances and economic growth (Faini, 2006; World Bank, 2006; Barajas et al., 2009), while others find a zero or negative relationship (Chami et al., 2003; IMF, 2005; Giuliano and Ruiz-Arranz, 2005).

Studies using country-level data face inherent challenges in conclusively establishing causal impacts of remittances on national-level outcomes. Studies using data at the micro (household or individual) level can often delineate causal pathways more convincingly, and can also shed light on remittance impacts with greater detail and nuance.

Many papers argue that remittances rarely fund productive investments, and instead mainly allow higher consumption: for example, see Brown and Ahlburg (1999), and references cited in Durand et al. (1996). However, others have found that migration and remittance receipts are positively correlated with various types of household investments in developing countries. Examples include Brown (1994), Massey and Parrado (1998), McCormick and Wahba (2001), Dustmann and Kirchkamp (2002), Woodruff and Zenteno (2007), and Mesnard (2004) on entrepreneurship and small business investment in a variety of countries; Adams (1998) on agricultural land in Pakistan; Taylor et al. (2003) on agricultural investment in China; Cox-Edwards and Ureta (2003) and Adams (2005) on schooling investments in El Salvador and Guatemala, respectively; and others. (Of course, neither consumption nor investment should be assumed a priori to be a 'better' use of remittances. It could be optimal for households to use remittances mainly on consumption, particularly if they are starting from very low consumption levels.)

A key methodological concern with existing work that attempts to understand effects on households is that remittances are not randomly allocated across households. In general, therefore, any observed relationship between migration or remittances and household outcomes may simply be due to unobserved third factors, or reverse causation. A more recent research literature on the impacts of migration (and the associated remittance flows) seeks to go beyond establishing correlations (as interesting as they may be), and pays close attention to establishing causal impacts on outcomes of interest.

An experimental approach to establishing causal impacts of migration and remittances would randomly assign migration opportunities (or fluctuations in the size of remittances), and examine how households or localities in the migrant-source country are affected. While there are substantial practical obstacles to conducting such experiments, a number of studies have identified situations in the real world – or 'natural experiments' – that in key respects approximate the randomized experiment just described.

One type of natural experimental study involves taking advantage of lotteries that migration destination countries have implemented to decide which of many applicants will receive a limited number of immigration visas. Lottery winners can then be compared with lottery losers, and any differences between the groups can be interpreted as due to differences in the opportunity to migrate. A number of papers have measured impacts of winning lotteries for immigration visas to New Zealand from Pacific island nations. Gibson et al. (2010) finds that Tongans moving to New Zealand due to winning the lottery increase their income 263% within the first year of moving, and also show improved mental health (Stillman et al., 2009), compared with lottery losers.

Gibson et al. (2011) then examine the impact of migrating due to visa lottery winning on household members remaining behind in Tonga. They find that per capita income and consumption of remaining household members are actually lower for left-behind household members of lottery winners, compared with similar individuals in lottery-loser households. This appears to be due to the fact that migrants send home lower amounts in remittances than they were earning domestically prior to migration. This negative finding does not appear universal, however. Gibson et al. (2013) conduct a similar analysis among Samoan households with and without winners in the New Zealand immigration visa lottery, finding that migration due to winning the visa lottery led to lower poverty rates and higher household incomes among left-behind household members.

Another natural experimental approach to establishing the impact of migration and remittances was implemented by Clemens and Tiongson (2013). Their focus is on Filipinos applying to migrate to Korea for temporary contract work. Their analysis exploits the fact that eligibility for this migration opportunity was conditional on receiving a certain minimum score on a Korean language test. Applicants scoring at the score cutoff or above were deemed eligible, and those scoring below were not. Their analysis involves comparing applicants who scored at or just above the Korean test score cutoff, and those scoring just below, on the basis that scoring just above or just below is as good as randomly determined. They find that eligibility for this migration opportunity on the basis of the Korean test score leads to large increases in the likelihood of international labor migration. The origin households of successful applicants in turn receive higher remittances, have higher expenditures, and invest more in children's human capital 3–5 years later.

Another revealing type of natural experimental analysis takes advantage of shocks to the economic conditions of migrants, and examines how origin households are affected. Yang and Martinez (2005) and Yang (2008b) take advantage of the fact that a nonnegligible fraction of households in the Philippines have one or more members working overseas at any one time. These overseas Filipinos work in dozens of foreign countries, many of which experienced sudden changes in exchange rates due to the 1997 Asian financial crisis. These exchange rate changes were unexpected and varied in magnitude across overseas Filipinos' locations. The net result was large variation in the size of the exchange rate shock experienced by migrants across source households. Taking advantage of this variation in the size of migrant exchange rate shocks, these papers examine the impact of the shocks on changes in outcomes in migrants' origin households. Yang (2008b) shows that more positive exchange rate shocks (from the standpoint of the migrant, appreciations of the overseas currencies in which they earn vs the Philippine currency) lead to increases in remittances sent home. Households whose migrants experience more favorable exchange rate shocks raise their nonconsumption disbursements in several areas likely to be investment related – in particular, educational expenditures – and show enhanced participation in entrepreneurial activities. Households raise hours worked in self-employment, and become more likely to start relatively capital-intensive household enterprises like transportation/communication services and manufacturing. By contrast, there is no identifiable effect of the exchange rate shocks on current household consumption. Yang and Martinez (2005) shows that these positive migrant exchange rate shocks also lead to lower poverty rates among migrant origin households.

One question that is often raised is whether remittance lowers recipients' incentive to work (sometimes referred to as a 'dependency' effect of remittances). Across studies, there is little evidence of such an effect. Gibson et al. (2011) find no statistically significant effect of migration due to visa lottery winning on labor supply of left-behind household members. Yang (2008b) find no effect of migrants' exchange rate shocks on wage labor in origin households, and actually finds a positive effect on hours worked in self-employment. The Clemens and Tiongson (2013) study also finds no effect of labor migration to Korea on labor supply of nonmigrant origin household members.

Insurance Role of Remittances

Remittances may also bring benefits to origin households of migrants by serving an insurance role. Households in developing countries are exposed to a variety of types of risk, such as from shocks to weather or other determinants of agricultural productivity, economic fluctuations of other sorts, or adverse health events within the household. Overseas migrants could respond to adverse events in origin households by sending assistance in the form of increased remittances. Such insurance provided by migrants could help origin households maintain human capital investments, encourage them to adopt new (and riskier) production technologies or entrepreneurial activities.

Remittance flows in the aggregate do appear to rise in response to negative shocks at the country level. Mishra (2005) examines aggregate remittances in 13 Caribbean countries from 1980 to 2002 and finds that every 1% decrease in GDP is associated with a 3% increase in remittances 2 years later. Yang (2008a) examines the impact of hurricanes on international financial flows using country-level data, and finds that for poorer developing countries, remittances rise after countries are hit by hurricanes, and amounting to about one-fifth of the value of hurricane damages (a response about one-quarter as large as the response of foreign aid).

Household-level analyses come to similar conclusions. For example, Yang and Choi (2007) ask whether migrant remittances serve as insurance by focusing on responses to income fluctuations driven by weather in the Philippines. Among households with migrant members, they find that remittances rise when incomes fall due to negative weather shocks. The amount of insurance provided is large, with about three-fifths of declines in income replaced by new remittances sent by migrants.

Concluding Thoughts

Remittances will likely remain one of the most important types of international financial flows to developing countries. Increasing competition in the money transfer industry, leading to declines in remittance transaction costs, will drive continued strong growth of remittances. Innovations such as cell phone-based remittance services will make sending remittances more

and more convenient for migrants. The existing empirical evidence suggests that migrants are likely to respond to the reductions in transaction costs and increases in convenience by sending substantially more remittances in dollar terms (Aycinena et al., 2010.) As a result, remittances are projected to continue to grow in the coming years, reaching $540 billion in 2016 (Ratha et al., 2013).

There are attractive prospects for continued remittance-related innovation on the part of money transmitters and financial institutions, and collaborations with academics and the nonprofit and government sectors. One direction for research is on the extent to which migrants value control over how recipients use remittances, for which there is emerging new evidence, for example in the area of control over savings in the home country (Ashraf et al., forthcoming). It should be useful to explore the demand for and impact of improving migrant control over other remittance uses, such as human capital investments or investments in small enterprises. Such innovations may lead to enhanced impacts on economic development outcomes in home areas, and may also encourage migrants to send more remittances.

Another area where future investigations might focus is on reasons why remittances tend to be sent in low-value transactions, at high frequencies. This pattern is a puzzle, because of substantial per-transaction remittance fees. For example, remittances examined in Yang's (2011) sample, remittances to El Salvador typically incurred a flat fee of $9 or $10 per transaction. An open question is why remitters fail to minimize fees paid by sending large amounts relatively rarely. There are a number of possible explanations for low-value, high-frequency transactions, such as liquidity constraints on the part of senders, self-control problems on the part of senders or recipients, or risk of theft or loss on either the sender or recipient side of the transaction. Valuable future work could seek to shed light on the likely causes of this very prominent pattern in remittance sending behavior.

Notwithstanding recent advances in our knowledge on migration, remittances, and their impacts, much more remains to be learned. We are likely to see major advances on remittance-related questions in the coming years. It remains a fruitful area for future research and experimentation.

International Migration by Ethnic Chinese

Emmanuel Ma Mung, CNRS, University of Poitiers, Poitiers, France

Abstract

The international migration of ethnic Chinese started to be numerically significant more than a century ago. It continued into contemporary times, mainly from continental China, but also from numerous countries in Southeast Asia where the first migrants settled. It is, therefore, not easy to assess the extent of this migration. However, their number can be estimated to 40–45 million. Two morphological characteristics lead to the definition of this migration as a 'diaspora': first, the multipolarity of the migration (migration toward several countries of destination) and second, the interpolarity of relations, that is, the fact that there are migratory, economic, and cultural ties between individuals who have settled in different countries. The diaspora-like character of this migration has led to the development of migratory, economic, and financial networks, which play a growing role worldwide, particularly in China and Southeast Asia.

The mass international Chinese migration began in the middle of the nineteenth century and today makes up 40–45 million people. It has evolved toward a diasporic configuration characterized by a multipolarity of migration and an interpolarity of relations in which networks play an important role and explain the economic efficiency of this diaspora. The revival of migrations from continental China has reinforced the diaspora and modified its composition and role.

The Migration from China

For centuries, or even millenniums, there has been a migration from China to Southeast Asia. These migrations mainly comprise an economic, political, or military urban elite. The Chinese migration really reached its peak in the middle of the nineteenth century when the combination of several factors made people leave. It was the result of the two Opium Wars, the Taiping Rebellion, the abolition of slavery, and the colonial enhancement of Southeast Asia by the English, the Dutch, and the French.

The two Opium Wars (1840–42 and 1856–60) and the Taiping Rebellion (1860–65) provoked tremendous social change and terrible famines, especially in the southern provinces, which are principal centers of departure even today. The progressive abolition of slavery during the first half of the nineteenth century brought about a demand for cheap labor in order to replace slave work in former slavery countries. But above all, the colonization of Southeast Asia and the development of new English, French, and Dutch colonies (Indochina, Indonesia, Malaysia, Singapore, and so on) also created a demand for workers in plantations (hevea, pepper plant, sugarcane, tobacco, and others) and in mines, a demand that was no longer filled by slavers or by local labor.

From then on, the geography of international Chinese migration was maintained for a long time, almost exclusively affecting the southern provinces of continental China and mainly spreading into Southeast Asia and into former slavery areas. This geography still plays a fundamental role in the general distribution of migration today, although there have also been substantial modifications. As a result of the treaties of the Opium Wars, the creation of the 'coolie trade' allowed colonial powers to hire workers in order to develop their dependent territories. The coolie trade produced flows of departure toward the Caribbean, the Indian Ocean islands, and Polynesia, but especially toward Southeast Asia. These workers were, for the most part, landless peasants. They were among the poorest and saw in these contracts, however miserable, the possibility for them and for their families to survive. The large majority of workers came from the southern provinces of China (Guangdong, Fujian).

Within 25 years, from 1876 to 1901, 4 850 000 emigrants, a considerable figure, are assumed to have passed in transit through ports in southern China. During that time, the number of people belonging to the Chinese diaspora was estimated at 8 million, most of whom were found in the Nan Yang areas (South China Sea) of Asia. Moreover, several dozens of thousands of people were scattered over the insular constellations of the Indian and Pacific Oceans, some hundreds of thousands went to the eastern rim of the Pacific Ocean, from Canada to Chile, and also to the Caribbean islands, in particular to Cuba and Jamaica.

Chinese International Migration Today

The ancientness of the migration, interracial marriages, the constant flow of migration, and the fact that the ethnic Chinese usually take the nationality of their receiving countries make an accurate measure of the extent of the diaspora difficult, because it is hard to determine what an 'ethnic Chinese' is. What differentiates ethnic identity from other social identities (professional, religious, and so on) is, as Max Weber states, the shared belief in a common origin, whether it is real or imagined. Ethnic identity is, therefore, a social construction not a natural one. It is still a valid criterion for defining a population because this belief strongly configures the relationships among individuals themselves and thus determines specific social behaviors with important effects on economic, political, and cultural patterns.

Bearing these considerations in mind, one can estimate the world distribution of ethnic Chinese from various sources (national censuses; Institute of Chinese Studies of Ohio State

University, Records of Overseas Compatriot Population Distribution of the Republic of China, press articles, research articles). From these numerous and diverse estimates, one can consider the number of ethnic Chinese in the world to be around 40–45 millions (see Table 1).

Table 1 Distribution of ethnic Chinese in 2010 (estimated in thousands, countries of more than 10 000 ethnic Chinese)

Asia	30 000–35 000
Thailand	9400
Indonesia	8800
Malaysia	6960
Singapore	2800
Vietnam	1300
Philippines	1150
Myanmar	1100
South Korea	690
Japan	660
Cambodia	340
Kazakhstan	300
Laos	190

Algeria	30
Mauritius	27
Réunion	25
Zimbabwe	10
Sudan	10
Total	40 000–45 000

Sources: Various, including national censuses; Institute of Chinese Studies, Ohio State, University; Records of Overseas Compatriot Population Distribution, Republic of China; press articles; research articles.

Ethnic Chinese are present in nearly every part of the world. One can note the presence of more than 10 000 individuals in more than 55 countries, 100 000 in nearly 24 countries, and a million individuals in at least 9 countries. The majority (75%) lives in Asia, but their presence there is proportionally less important than it was 50 years ago (96%). There is now a redeployment of the diaspora, notably toward the nonAsian Pacific (North America, Australia), Europe, and Latin America and Africa.

Ethnic Chinese were estimated to be around 20 million at the beginning of the 1980s, the numbers of the Chinese diaspora would thus have doubled in about 30 years. This impressive increase is due to the natural growth of this population but especially by the revival of migrations from mainland China.

Revival of Migrations from Mainland China

The economic opening of China was accompanied with liberalization of conditions to emigrate and in 2006 more than 20 millions people has a passport. The annual number of Chinese migrants according to the census figures in Beijing increased rapidly from 57 000 in 1982 to 757 000 in 2000. The annual flow of entries of Chinese citizens in the countries of OECD rose from 140 000 in 1995 to 335 000 in 2000, and 539 000 in 2008. These flows of new migrants have affected the already settled groups.

Southern Chinese provinces – Guangdong, Fujian, and Zhejiang – are still the main source of migrants as evident from the large numbers of clandestine migrants going to Europe from these. But since the 1990s, migrants have been arriving from new places of origin, such as great urban areas like Beijing, Tianjin, and Shanghai, but above all, the Dongbei region comprising the northeast provinces of Heilongjiang and Liaoning, and Hubei in central China. One characteristic of this migration flow is the increasing number of female migrants.

A new migratory phenomenon linked to the increase in the level of education in the country is the emigration of skilled and high-skilled people especially of students. The Chinese authorities encouraged during the 1990s students to study abroad. In 2001, around 150 000 of them went abroad, mainly

to the Western countries. And at the beginning of the 2000s, they were 460 000, half of them were in the United States and 20% in Europe.

Migrations from China or from other settling countries of the Chinese diaspora are oriented more and more to the developed countries. According to national censuses, from the beginning of the 1990s to the mid-2000s the number of Chinese in overseas increases of 1.7 million (from 1.6 million to 3.3 million) in the United States and of 1 million in Canada. In Japan, it is multiplied by four to reach 610 000, and in Western Europe (France, United Kingdom, Italy, Spain) the number increase from 361 000 to 783 000, and Australia now has 670 000. New settling areas have appeared, such as the Central and Eastern European countries. One can find there several tens of thousands of Chinese migrants, and in Eastern Siberia several hundreds of thousands of them, including farmers who cultivate land deserted by their Soviet predecessors. Other new destinations are Central Asia, and more recently Africa and Latin America.

Since the 1990s, temporary and contractual migrations developed in relation with Chinese companies working abroad and involved in the exploitation of raw materials (oil, ores, wood, etc.) and the construction of infrastructures for that purpose. In addition, they are engaged in large scale projects involving the building of equipments in public works and telecommunications and the distribution of electricity in particular in Africa. These new type of migrations are also carried out by Chinese agencies, which sale this labor force to companies in different countries through bilateral agreements in different parts of the world. In 2004, there were 597 000 such migrants, the large majority of them were in Asia and Africa.

Over the last decade the migration of merchants has developed rapidly worldwide, reflecting the development in the production of consumer goods in China. They distribute products 'made in China' consisting of textile, bicycles, motor cycles, tools, electric household appliances, electronic goods, data-processing equipments, computer, etc. One can find these new Chinese merchants in Western Europe (mainly in France, Italy, and Spain), in Central and Eastern Europe (notably Romania, Bulgaria, Hungary, and the Czech Republic), etc. In Africa, the phenomenon is highly visible.

Mostly, this merchant migration is resulted by the opening of wholesale centers to supply retailers, whether Chinese or native. In Aubervilliers a town near Paris, several hundreds of Chinese wholesalers are settled in a dedicated area. The same is true of Italy (Naples) and in Spain (Madrid). The same scene is repeated in South Africa, where one of the largest wholesale centers is located in Johannesburg, Nigeria, Ghana, Cameroon, Togo, Senegal. Apart from these wholesalers, one also finds many retailers established in the main cities. Some have also settled in cities of intermediate sizes or in small towns.

The Chinese Diaspora

The existence and the development of migratory, economic, informational, but also affective and emotional relations between the various poles of settlement, at the local and global scale, circumscribe a social entity of which the unit is given by the subjective belief of the people in a common origin – China – which is the base of a collective identity. It is in this sense that one can speak of Chinese diaspora. The Chinese overseas constitute a diaspora, which is characterized – morphologically – by the multipolarization of the migration (installation in several countries) and the interpolarity of the relations; i.e., the existence of relations between the various places of settlement.

This diaspora is 'entrepreneurial' in the sense that enterprises ensure its reproduction as social body. Companies play a crucial role with regard to employment. The majority of the ethnic Chinese work in these companies and these companies employ mainly ethnic Chinese.

Chinese migrations gave rise in most settling countries to an economic organization made up by small firms articulated between them on the local scale in the fields of supplying, financing, or labor. They form kinds of local economic clusters, often related ones to others at international scale.

This economic organization as 'entrepreneurial diaspora' has important effects on Chinese migrations, because these movements meet more the demand for labor of the ethnic Chinese companies than the demand of the general labor market. The multiplication of these companies encourages an immigration that contributes to their development. In return, it reinforces the labor demand, and consequently migrations.

Multipolarity of the Migration

Since the nineteenth century, Chinese migration has had a pronounced multipolar feature because of its direction toward many territories in Southeast Asia, the American continent, Polynesia, the Indian Ocean, the Caribbean, South Africa and, in a more modest way, in Europe. Throughout the twentieth century, a change in the destinations and a reinforcement of the Chinese presence was noticeable. As previously stated, the presence of more than 10 000 overseas Chinese in each of more than 55 countries is recorded, with more than 1 million people in at least nine countries. One of the main features of this distribution is therefore a strong multipolarity of the migration. The other feature of the international Chinese migration is a strong interpolarity of relations.

Interpolarity of Relations

Interpolar migrations are often linked to major geographical trouble. The wars in Vietnam, Laos, and Cambodia, and the political takeover by totalitarian regimes that followed them, caused the departure of more than 3 million people, most of whom where first or later generations of Chinese origin. For the most part, they joined already established communities in Europe, North America, Asia, or Australasia by means of diverse itineraries, sometimes passing through various receiving countries. During the 1990s in Indonesia, where more than 8 million ethnic Chinese are recorded, demonstrations against the government and President Suharto have at times degenerated into anti-Chinese pogroms. From 100 000 to 125 000 ethnic Chinese are thought to have left Indonesia within 1 year, for the most part heading toward Singapore, Malaysia, Australia, or even Hong Kong. Fortunately, all migration is not due to

dramatic events, but is rather a search for better opportunities elsewhere. This is the case for the Chinese who settled in Italy or in Spain, among whom a good part came from France in the 1980s and 1990s because the French government immigration laws became ever stricter, and because of the relatively greater freedom in the new receiving countries at this moment. It is worth noting that these Chinese also came to join small communities that had already been settled for several decades. This also happened between France and the Netherlands during the period between the two world wars.

The diversity of the national origins of the Chinese within the receiving countries is a good indicator of the interpolarity of the migrations. In France, and today also in Spain and in Great Britain, more than 20 different national origins are recorded among the ethnic Chinese, with even a greater number in North America: nearly 30 in Montreal alone, for instance, and 40 in the United States.

These interpolar migrations are the basis of relations between the different settling poles. They represent the networks of movement of persons, materials, and nonmaterial values (goods, money, information, social norms and codes, cultural models). The classic example is the establishment of trading networks between China and the different receiving countries of the diaspora. These networks have been strengthened considerably since the opening of the Chinese economy. On a more subtle scale, such migration represents an extension of distributional networks in the various areas of settlement in a given country, as long as the migration spreads. The most interesting point is the growth of trading networks among the different receiving countries. The way a diaspora works, it induces a diversification of the geographical areas of supply and distribution. In grocery stores, to take a simple example, specialized products came from several dozen different countries in addition to continental China, namely from Taiwan, Singapore or Hong Kong, Hawaii, Thailand, Brazil, and even Spain and California. A study made out in an Asian supermarket in Paris revealed that the products came from 37 different countries that had an ethnic Chinese population. A similar study from a Chinese supermarket in San Diego (California) revealed more than 40 different countries of origin.

The existence of interpolar relations can allow people engaged in business to move from one country to another when working conditions worsen. This explains why Sino–Indonesian capital was particularly withdrawn toward Singapore and Thailand in the 1960s and 1970s. This is also the reason why today there is a shift in capital from Southeast Asia to the American west coast in order to take advantage of economic opportunities (financial flow from Taiwan or Singapore) and vice versa.

Decisive Economic Effects

Southeast Asia makes up 75% of the number of individuals in the Chinese diaspora. The presence of these immigrants has asserted itself in the nineteenth century already, and it has been reinforced constantly ever since. At first, this immigration included labor force for mines and plantations, but it shifted quickly to small shopkeepers, craftsmen, and sometimes to manufacturers and businessmen. Already at the beginning of the twentieth century, the rice business and commercial distribution were operated by these immigrants or their descendants even in the most remote villages. Since then, their presence in economic activities has constantly been reinforced. In some Southeast Asian countries like Indonesia, Philippines, Thailand, Malaysia, and especially Singapore, the ethnic Chinese control is an important part of the private economy, the country trade, and the financial investments.

Since the opening of China, the Chinese diaspora has increasingly had important economical relations with this country. This has contributed in a very decisive way to the spectacular development of this country since the mid-1980s. Practically disappeared from the 1950s, the remittances of emigrants started again in the 1980s and increased in an impressive way: $US175 millions in 1990, $US5.2 billions in 2000, and $US51.3 billions in 2010, according to the World Bank. In these remittances are added an important part of the foreign direct investments (FDI) in China realized by companies and financial groups belonging to ethnic Chinese. In 2001, the diaspora would have contributed for 63% of FDI ($US30 billions), and in 2004, for 60% of FDI ($US36 billion). The economic takeoff of China is thus widely connected to these transfers and the most economically developed provinces are also the ones of strong migratory tradition.

Conclusion

The international migration of ethnic Chinese, which started in the mid-nineteenth century, has evolved into a diaspora-type configuration. Today, this migration constitutes the most important population in a diaspora (40–45 million people). Networks play an essential role in such a diaspora. Even if today it seems too powerful and rich, one should remember that originally it was composed of labor migration, and that this remains an element to this day. Current migrants are still mainly proletarians.

This migration, like other migrations, form new social groups – the diasporas – settled on transnational territory. A diaspora is based on an identity of ethnic features. This ethnic consideration does not exclude other elements. Studies of the Chinese diaspora constantly remind the investigator of the singularities of the individuals who have different national and/or geographical origins and speak many different languages. In everyday life, ethnic Chinese meet fellowmen who are nevertheless different. Therefore, an 'internal' cosmopolitanism is at work in the diaspora, which guarantees multiple allegiances across the different countries where the diaspora has been established, as well as with China.

International Migration by Ethnic South and Southeast Asians

Abstract

South and Southeast Asia are currently home to one-third of the world's population and as such are one of the main global reservoirs of potential international migrants in the contemporary context of rapid globalization. Moreover, within the region the last two decades have seen international migration become part of the calculus of choice of an increasing proportion of residents in the region due to education, internationalization of labor markets, and transformation of transport and communication systems. However, while the region contains several of the world's largest 'labor surplus' nations and hence potentially (as well as actually) several of the globes' major source areas of international migrants, the patterns of international movement influencing the region are more complex than a simple 'south–north' flow. Although the latter is significant, it has to be recognized not only that south–north migration takes various forms and is a complex two-way process, but there are also important migration flows within the Asian region. The types of migration examined include permanent resettlement, refugee movement, labor migrations, student migrations, and undocumented migrations. The article summarizes these patterns and then proceeds to examine some of the characteristics of the migrants themselves. Here, attention is focused on the increasing levels of involvement of women in the movement and their selectivity in terms of skill and education. It is pointed out that while there are important flows of skilled people, there are also major flows of unskilled migrants (especially migrant workers) out of the labor surplus nations of the region. The relevance of neoclassical economic theories of migration is assessed and such a theory is seen to be only partial in its explanation. Other elements considered to be important are the proliferation of social networks and the development of an immigration industry in the region. Government in both sending and receiving nations are also becoming increasingly influential in shaping international migration. A number of issues relating to international migration in the region are then addressed. These include the scale and impact of remittances sent home by migrants from the region who are abroad, issues relating to the protection and vulnerability to exploitation of migrants, the role of intermediaries in the migration process, the level of trafficking, people smuggling, and undocumented migration in the region, the brain drain, the relationship between migration and economic development, and the formation of ethnic enclaves in destination countries.

Introduction

South (including the countries of India, Pakistan, Bangladesh, and Sri Lanka) and Southeast (the countries of Indonesia, the Philippines, Thailand, Vietnam, Singapore, Malaysia, Brunei, Cambodia, Laos, and Myanmar) Asia were home to 33.1% of the world's population in 2013 (2367.8 million persons) (United Nations, 2013a). Moreover, the region has experienced massive population change over recent decades (Williams and Guest, 2012; Veron, 2008). The rapid increase in population movement between countries that has accompanied the process of globalization has affected all of the countries of the region. There has been a major increase in the levels, complexity, and impact of international migration. While two decades ago mobility was limited to a selected small proportion of residents in the region, it is now within the calculus of choice of a major part of the population as they weigh up their life chances. With the increase in movement has come an increased awareness of it, and intervention to influence it, by governments in the region. This article seeks to summarize the evolving patterns of movement and address some of the major issues relating to it.

The increasing significance of international migration of South and Southeast Asians is evident in Table 1. This indicates that while the world's population currently live in South and Southeast Asian countries – 2367.8 million people – a further 55 million people born in these countries are currently living in different countries. The largest diaspora (14.17 million) is of Indians, while the countries where the diaspora is largest in relation to their resident population are Laos, Afghanistan, Brunei, and Bhutan. These measurements of diaspora are, however, partial because

- they exclude second and later generations born in destination countries,
- they only include countries of destination, which collect information on the foreign-born in their census.

Hence, estimates of the actual size of South and Southeast Asian diaspora are generally substantially larger than those in Table 1.

Patterns

The data available to examine international migration in South and Southeast Asia are limited. The increase in significance and intensity of movement has outpaced the development of data systems to measure it. Moreover, undocumented migration in the region is arguably as great in scale as legal migration, and by definition, the information relating to that movement is very limited. While there is a great deal of complexity in the spatial patterning of the movement, the degree of permanency, the characteristics of movers and its legality, it is possible to identify three main subsystems of movement in the region. These include a so-called south–north, more or less permanent, flow to developed countries, a predominantly temporary labor flow

Table 1 South and Southeast Asia: migration stocks in other countries, 2013

Country of origin	*Migrant stocks in other countries*	*Residents in origin*	*Migrants as % of residents*	*Migrants as % of global total*
Afghanistan	5 109 921	30 552 000	16.73	2.21

to the Middle East, and a third set of 'south–south' interactions within the region. Each subsystem involves different balances of forced and nonforced movement, males and females, permanent and nonpermanent, documented and undocumented, labor related and other movement, etc.

South–north movement has recently become the most dominant global international migration flows (United Nations, 2013c), and South and Southeast Asia is one of the dominant origin areas of such flows. In the largest nation in the region, the Indian government in May 2012 estimated the size of its diaspora at 21.9 million. (Source: Ministry of Overseas Indian Affairs, http://moia.gov.in/writereaddata/pdf/NRISPIOS-Data(15-06012) new pdf (accessed 08.11.13.).) However, other countries in the region also have large diasporas and many of them are in OECD countries as a result of so-called south–north migration. **Table 2** presents estimates of the numbers of South and Southeast Asian migrants in more developed countries. These are underestimates of the impact of immigration because the data are obviously incomplete; undocumented migrants are excluded and the children born overseas to migrants and later generations are not included. Nevertheless, the scale of the movement can be appreciated.

However, more or less permanent settlement in North countries is not the only type of movement out of South and Southeast Asia. International labor migration whereby workers from the region move to other countries to work, usually under contract, for a set period (usually around 2 years) before returning to their home country has expanded in the last two decades. One of the major streams of this type out of the region is directed toward the Middle East. There has been a long tradition of South Asians working in that region, which extends back to colonial times; but the steep increase in oil prices after 1973 saw massive flows of foreign exchange into the region that fostered massive infrastructure construction, which in turn saw the expansion of recruitment of foreign workers initially

from South Asia but later from Southeast Asia. In the late 1980s, this movement changed to include more women and service workers. Again, data are poor since many Middle Eastern countries do not release information on migrant workers due to the sensitivity attached to heavy reliance on foreign labor in several countries where these workers in some cases outnumber local workers. Nevertheless, Table 3 presents some information for the main labor-exporting countries. The bulk of migrant workers from Southeast Asia are unskilled, while South Asia has sent both skilled and unskilled workers. Female domestic servants have become more significant in the movement over time, especially those from Indonesia, the Philippines, and Sri Lanka.

In the 1980s and 1990s, there was a growing tempo of movement of international labor migrants to Asian destinations, including other countries in the Southeast Asian region. This is evident in Table 4, which consolidates estimates of the stocks of overseas migrant workers from the various nations of South and Southeast Asia. These indicate that for many the main destination is another Asian nation. In fact, several of the East and Southeast Asian nations, which began their transitions to low fertility in the 1980s and 1970s, have suffered significant labor shortages in recent years. This has been a function of both rapid economic expansion and the declining numbers of new entrants into their workforces due to low fertility. This has been accompanied by a distinct segmentation of their labor forces whereby local workers have eschewed entry into low-income, low-status jobs, which have created niches for overseas migrant workers in these areas. Hence particular industries in particular Asian countries have become quite dependent on foreign labor. These include some activities in countries like Thailand and Malaysia, which themselves are supplying migrant workers to Japan and Taiwan. Hence in Thailand the rice milling and fishing industries are heavily reliant on labor from Myanmar, while in Malaysia the plantation and forestry

industries rely upon gaining workers from Indonesia, the Philippines, and Bangladesh.

It is apparent then that one can recognize three distinct subsystems in South and Southeast Asian migration. One has involved movement to the so-called northern nations; another links the region to the Middle East; while a third involves intra-Asia movement. While, permanent settlement in the case of the first subsystem and labor migration in the case of the second, two are dominant, there are a number of other forms of international movement involved in the subsystems. Dealing first with the south–north movement, a most important factor was the abolition of racially biased immigrant selection policies in the main immigration countries (United States, Canada, Australia, etc.) in the 1960s and 1970s. Immigration policies were developed in which selection was based upon skill/education and/or family linkages as well as acceptance of refugee/humanitarian migrants. Hitherto migrants from South and Southeast Asia could not compete on an equal basis for migrant places with people from Europe. In addition, migration flowed along linkages established by colonial rule (e.g., Indians and Pakistanis to the UK, Indonesians to the Netherlands, etc.) or by military involvement (Koreans to the United States, etc.).

An important element in the south–north movement, as well as migration within Asia, has been that of the refugees. Table 5 shows the current stock of refugees in countries in the region. While there have been several such flows over the last half century, two have been on a particularly large scale and have differed substantially in type. The outflow of refugees from Indochina following reunification of Vietnam in 1975 was predominantly initially to other Asian (especially Southeast Asian) nations. This involved more than 2 million people the vast majority of whom have been settled in third countries (predominantly in the 'north') or repatriated back to their home countries. These movements have resulted in substantial subsequent migration since these refugee settlers functioned as anchors in destinations to bring other family members to these destinations, often using the family reunification components of migration programs.

The second major refugee migration occurred from Afghanistan, especially into the neighboring nations of Pakistan and Iran. This involved several million people most of whom were not settled in third countries or repatriated but stayed for long periods in their countries of temporary asylum. There have been many smaller but nevertheless significant movements, mostly involving movement into neighboring countries – Myanmar into Thailand, Tibet into India, Bangladesh into India, the Philippines into Malaysia, etc.

Another strand in the south–north migration has been the acceleration in the migration of students to undertake secondary but especially tertiary education. Table 6, for example, provides data on the percentage of foreign students from Asia studying in tertiary institutions in some northern countries. In Australia, for example, over the 1983–2013 period the number of overseas students increased from 9098 to 462 411 with almost half of the latter being from South and Southeast Asia. There is a strong connection between such movement and eventual settlement in the destination nation. Indeed, gaining an educational qualification in the 'north' country can facilitate entry as a permanent settler.

A related element in the intra-Asian subsystem involves the movement of trainees from labor surplus nations like Indonesia, Thailand, and the Philippines to countries with shortages such as Japan and Korea. The movement ostensibly is for workers of multinational companies in the former countries to spend a period in the home country of the companies to gain training. There has been discussion of the extent to which companies are using this system to import unskilled or semiskilled workers when government policy prevents such movement.

While the net effect of the south–north movement is emphatically in favor of the north, the flow in the opposite direction is not to be ignored. This in part involves former emigrants returning to their home country, but in the case of some Southeast Asian nations also involves natives of northern countries to meet the demands for skilled workers in areas like accountancy, engineering, management, etc., which cannot be met locally. Most of the latter will remain only temporarily in the Asian country. The fact that there is return migration into Asian countries from the north, however, is often neglected. It

often can take the form of a 'reverse brain drain' involving highly qualified people who return and take up important positions in the economy or government of their home country.

Obtaining estimates of international migration in the South and Southeast Asian regions is very difficult. Data collection systems are not generally well developed and there is a high level of undocumented migration. The highly complex nature of the movement needs to be stressed as does the fact that there are complex linkages between the different types of movement.

The Migrants

Migration is always a selective process in that the groups of people who move differ from those who are left behind or those which they join at the destination. Each of the three main subsystems briefly described above is distinctive not just in terms of the countries involved, but also the types of people who move. The south–north migration can generally be characterized as being selective of the better-educated and skilled populations since entry criteria in the destination countries usually require this, although 'business' migration programs involving the investment of minimum levels of personal wealth at the destination are increasingly common. Under family reunification and refugee/humanitarian programs and the United States Quota Program, there are some, but limited, opportunities for unskilled people to move but the overall selectivity remains. One characteristic of the south–north movement is the increasing involvement of women such that in several northern countries women immigrants from the region (especially Southeast Asia) outnumber their male counterparts.

The composition of the flows in the Asian and Middle East subsystems is quite different. While there are certainly exceptions (these include some of the flows out of South Asia and the Philippines), the out-movements are dominated by unskilled workers. These are directed at particular labor market niches at the destination, which due to low wages or low status are unable to attract local workers. Several of these flows are selective of women so that in some sending countries (e.g., Sri Lanka, Indonesia, and the Philippines) women outnumber men among the outgoing migrant workers. These women are especially directed to a number of specific occupations, which sometimes make them vulnerable to exploitation. These especially include work not only as domestics in private homes in destination countries but also in some cases are associated with the so-called entertainment industry. In some countries (e.g., the Philippines), it has been found that migrant workers sometimes take up jobs in the destination country, which are at a level below their qualifications.

The Process

There can be no doubt that the level of international population movement in South and Southeast Asia has increased substantially over the last two decades. While in the 1970s the possibility of international migration was only within the reach of relatively few people in the region, it is now within the calculus of choice of a much larger number of people and a wider range of socioeconomic, cultural, and gender groups. Clearly the whole process of globalization, especially as it has impinged upon labor markets, has been an important factor. This has greatly increased the linkages between nations involving flows of goods, finance, ideas, etc., and it is inevitable that movements of people also have increased although the barriers erected by nation states to flows of people have been reduced.

Neoclassical economic explanations have relevance for migration in the region. South and Southeast Asia contain four of the 10 largest labor surplus countries in the world. The demographic and economic gradients between richer and poorer countries both globally and within Asia have increased over the last two decades so that there are steep differences not only in income and wages between nations, but also in the rate of increase of the working age populations. Labor importing economies are undergoing economic transformation from manufacturing to service-based economies and this is creating jobs for migrant workers. Labor shortages in areas like information technology, management, and a number of skilled areas not only are encouraging the development of international labor markets, but also the labor market segmentation referred to earlier is creating opportunities for migrant workers in low skilled, low paid, and low status areas. The South and Southeast Asian region is able to supply workers both in the skilled areas (from South Asia, the Philippines) and the unskilled occupations.

Nevertheless, the widening gaps between nations in population and economic growth, and income and wage differentials are not sufficient explanation of the burgeoning of migration in the region although they are an important component of any comprehensive accounting for it. There are a number of other elements, which are also involved. Among the most important is the development of social networks between origin and destination nations. Empirical research indicates that the majority of movers from the region migrate to join family and friends who migrated earlier to the destination. A large proportion of South and Southeast Asians now have social capital in countries other than their own in the form of a family member or friend who lives and/or works in those countries. Those linkages form important conduits along which international migration, both documented and undocumented, takes place. The development of ever cheaper and better transport and communication systems enhances the operation of these networks in initiating migration.

Another element involves the so-called migration industry, which has a long history in the region but has proliferated in recent times. This involves a plethora of immigration agents, recruiters, travel agents, travel providers, immigration officials, labor brokers, and other intermediaries who are involved in initiating and facilitating international migration. Part of this infrastructure are the people smugglers and traffickers who transport migrants outside of government regulations but it also involves many who operate within the law.

Another element is the greater involvement of government in international migration in the region. While governments in destination countries are predominantly concerned with controlling the numbers and characteristics of immigrants, those in sending countries are increasingly becoming involved

in the emigration process. Realization that international migration can relieve under- and unemployment at home and enhance foreign exchange earnings has seen governments in several nations intervene to encourage emigration and to protect the rights of their nationals living and/or working in other countries. Some countries have been active in encouraging former migrants with needed skills to return, while others have policies and programs to encourage their nationals in other countries to invest their earnings in their home countries.

Issues

The proliferation of international migration in South and Southeast Asia has seen the emergence of a number of significant issues both in the countries of origin and destination as well as among the migrants themselves and their families. One of the most debated of these relates to remittances – those money earned by migrants abroad that are sent to or brought back to the country of origin. There is debate as to the scale and impact of these financial flows, but the data relating to them are largely incomplete. This is because much of the flow does not pass through official channels. Nevertheless, it is clear that the impact of remittances can be considerable. Table 7, for example, shows the significance of reported remittances in relation to foreign exchange earnings from trade in three Southeast Asian countries. While global figures such as those in Table 7 understate the scale and impact of remittances nationally, there can be no doubt that their impact within regions of South and Southeast Asian countries is much greater. This is because migrants tend to be drawn from particular *regions* rather than randomly across the nation. Hence remittances tend to be focused on particular parts of countries such as Kerala in India or Flores in Indonesia. Moreover, these regions are often among the poorest in the origin countries and the remittances represent one of the few sources of investment in those regions. For example, a December 1999 report from the State Planning Committee of Laos indicates that remittances from abroad represented 28% of all household earnings in the Vientiane Valley compared with 25% from agriculture, 22% from wages, and 18% from business (Lintner, 2000: 48). However, remittances have also been seen to increase costs and widen income distribution in origin areas as well. There have been several interventions by governments in the region to encourage nationals overseas to put their earnings in national banks and to invest in their home countries as well as to encourage the sending of remittances to the home country.

Another important issue relates to the exploitation of migrants from the region. While it is incorrect to depict all such migrants as victims subject to exploitation, there can be no doubt that some groups are vulnerable to exploitation of a number of kinds. This is particularly the case among some groups of female migrants, especially those who work in occupations where protection is difficult like as domestic workers in private homes and in the entertainment industry. Those who are undocumented are especially vulnerable to exploitation, but lack of knowledge and local languages and customs can also increase vulnerability of immigrants. Governments of sending countries vary considerably in the efforts they have made to protect their nationals abroad. The Philippines, for example, leads the way in this area but even so significant exploitation still occurs. The issue of protection of

nationals overseas is most pressing, but governments find it difficult to interfere in the affairs of other countries. Accordingly, some of the most effective protection comes from the activities of nongovernment organizations and through informal networks established by the migrants. Exploitation of the migrants can occur in the process of movement when they may be forced to pay exorbitant amounts of money or suffer physical abuse. There have been several documented cases of undocumented migrants from the region losing their lives due to suffocation or drowning in the process of migration. At destinations, they can be subject to exploitation and discrimination especially if they are undocumented migrants. Such migrants are usually depicted as criminals rather than as victims of the groups that exploit them in the process of migration or at the destination.

The pressing issue of protection of migrants and migrant workers from the region is related to that of controlling the intermediaries in the migration process. While all such intermediaries do not operate outside of the law, a substantial number do. Indeed the involvement of crime syndicates in people smuggling and trafficking has increased exponentially and has become an important issue in international crime. The multinational nature of these groups makes them difficult to control and their influence is widespread, even involving officials involved in immigration. The thriving of such organizations is clearly related to the failure of documented migration systems and enhanced policing of migration is unlikely to solve the problem of undocumented migration. Improvement of official migration systems must be part of the increasing international effort to combat the people smuggling and trafficking, which is especially rife in South and Southeast Asia. In countries of origin there is a need for information programs, which provide potential migrants with detailed, accurate information about the costs of the migration process and the nature of the experience at the destination. Studies in several countries indicate that migrants are often poorly informed on both these counts and this can lead to them paying excessive amounts to move and having false expectations of the destination. The latter, for example, results in up to one-half of Indonesian women going to the Middle East to work as domestics, returning to Indonesia before their contract time has expired. There needs to be a crackdown on the activities of unscrupulous intermediaries in several countries.

The issue of south–north migration representing a 'brain drain' of skill and talent needed for development in the home countries is a longstanding one in the region. In several origin countries, however, the occupational profile of migrant workers is largely an unskilled and semiskilled one, so that movement out of a country like Indonesia certainly cannot be characterized as a brain drain. On the other hand, much of the movement out of countries like India, Pakistan, the Philippines, and Singapore is of skilled and highly educated groups. In those cases, however, the movement is not necessarily a net economic loss to the nation. Economic studies have shown that in some cases individuals have a net positive economic impact if they go overseas and remit money back to their home country rather than remain behind. In countries like India and the Philippines, there appears to be an over supply of some skilled groups in relation to the opportunities available locally. Nevertheless, there can be no doubt that the emigration of some skilled groups can be detrimental to local economies in some cases. With the globalization of labor markets, such mobility is inevitable. Some countries in the region (e.g., Pakistan) have put in place programs to encourage former emigrants with certain skills to return to their home country. The growth of India's information technology industry, for example, has lured some former emigrants to return.

With the increasing recognition of the significance of international migration's influence on economic development, the last decade has seen a growing interest of governments in adopting explicit policies to influence international migration. Table 8 shows that there has been an increase in the number of countries with explicit immigration policies and an increase in the number seeking to increase immigration levels. Moreover, the realization that in a favorable policy context emigration can enable development in origin areas has seen an increase in the number of countries with diaspora policies (Table 9).

The interrelationship between international migration and development in the region is much argued. There can be no doubt that international migration can have both positive and negative effects on the well-being of communities left behind. This presents a challenge to policy makers to put in place institutional structures, which maximize these benefits and minimize the negative effects. All empirical evidence points to the fact that there is little to be gained from policies and programs designed to stop population movement when there are economic imperatives behind that movement. The challenge is in creating policies and structures, which enhance the benefits of the movement.

There are a range of issues that relate to the experience of migrants from South and Southeast Asia in destination countries. Several groups settling in northern countries show a tendency to concentrate in particular communities or develop

ethnic enclaves, especially in major metropolitan areas. Debate on these ranges between those who see such areas as barriers to the adjustment of migrants and those who see them as having a cushioning effect in allowing migrants to adjust to life in the new country in a gradual way and with the support of community networks. Other issues relate to discrimination experienced by some groups in housing and job markets as well as nonrecognition of qualifications leading to occupational skidding and deskilling.

Conclusion

The South and Southeast Asian region represents one of the world's major reservoirs of potential international migrants accounting for more than one-quarter of the global population and several of its largest labor surplus economies. Until recently, the impact of international migration in the region has been limited, but it is now of significance in all countries in the region. Although fertility decline has been significant, the labor force in the region continues to grow rapidly. Economies in several countries in the region are also growing rapidly but all of the pressures, which have created greater movement in the last two decades than previously will continue to operate. Hence the twenty-first century will see an increase in the scale and complexity of movement out of, within, and into the region.

Abstract

Explicit research interest in the consanguinity between international organizations and education as a field of inquiry is a recent development. It has grown with the demise of formal colonialism and the rise of the economic liberalization that emerged, and advanced rapidly, in the wake of the Cold War. The development of new communication technologies that shrink both time and space have played a crucial role in these more recent efforts. They shape the demands that globalization, and the knowledge economy, places on international organizations as agents of global change.

Introduction

International organizations and education have often been intimately linked. Thus, for example, we can note the relationship between the Catholic Church and its rich tradition of scholarship and teaching in various parts of the world. We could also bring to mind the East India Company and the folding of education – particularly education in English – into its mercantilist involvement around the globe. Nevertheless, explicit research interest in the consanguinity between international organizations and education, particularly higher education, as a field of inquiry in itself is a relatively recent development (Altbach, 2010). It has grown with the demise of formal colonialism and the rise of the economic liberalization that emerged and advanced rapidly in the wake of the Cold War. The development of new communication technologies that shrank both time and space have played a crucial role in these more recent efforts and have come to shape the demands that our contemporary understanding of globalization, and the knowledge economy, place on education. It is the connection between these different, albeit related, strands of global, economic, and epistemological change that has compelled international organizations to play an increasingly active role first in education more broadly and now increasingly in the domain of higher education (Marginson, 2013).

Theoretical Approaches

Many methods have been invoked to understand the development and growth of education by international organizations tied primarily to the United Nations, but also to other organizations that bear a strong commitment to international social, cultural, scientific, and economic development. Following World War II, the efforts of international organizations were directed toward enabling previously colonial countries to modernize and establish capacities for full and equal participation in an international system. Thus, for example, UNESCO adopted in 1960 the Convention against Discrimination in Education. This convention called for a prohibition on all kinds of discrimination in access to education based on the right to education laid out as a fundamental human right in the Universal Declaration of Human Rights (Byani et al., 1994). Various theories were advanced both to promote this agenda and to provide a critique of it. Thus, if modernist theories sought to improve education as part of a global modernization project, neo-Marxist theories were critical of these efforts and saw them as promoting a new kind of colonialism and imperialism spurred by the interests of either countries wielding global power or dominant sections of society within nations themselves (Carnoy, 1974).

Furthermore, there was an effort to establish educational institutions as a component of the nation-building process within newly decolonized states; these were seen to be were part of the legitimizing process as these newly minted nation-states sought to develop in the mode of Western states. That said, however, the international organizations involved with education were often viewed with suspicion by the very nation-states that were seeking to develop though a Western conception of modernity and seen as tools in the hands of capitalist and parochial political power brokers rather than as agents of democratic change. This suspicion, for example, led India in the context of the Indo-Pakistan conflict around the war for Bangladeshi independence to end the functioning of the Peace Corps within its borders. In addition, most of the efforts of the international organizations involved with education were directed toward education at the primary and secondary levels with the goal of providing universal education to members of all the segments of society both within and across countries. Above all, at this stage, education was largely seen as a local interest, and international organizations saw themselves primarily as facilitators for providing universal access to primary and secondary education.

International Organizations as Educational Agents

The supportive educational role that international organizations played has changed with globalization, liberalization, and the knowledge economy that developed in the wake of the Cold War and the rapid growth of technological innovation. Emphasis has now shifted away from primary and secondary education to higher education, and international organizations – rather than being facilitators for national efforts at education – have become agents in educational reforms and the building and transformation of educational institutions around the globe. The relationship between universities and the world economy had been often noted, as by Manuel Castells (1994), but the focus

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92100-7

today is on preparing young men and women to work within a global knowledge economy.

In other words, the previous emphasis on educating for citizenship within a national ideological context and even the world economy in the context of the Cold War has shifted in the post-Cold War period toward educating for a global economy that relies heavily on the development and use of new information technologies (Torney-Purta et al., 2001). Thus, for example, the World Bank recently released a report titled *Skilling Up Vietnam: Preparing the Workforce for a Modern Market Economy*, which stresses that the nature of work in a modern market economy will need employees who display a mix of higher-quality cognitive, behavioral, and technical ability. Furthermore, the new and emerging technologies vital to the modern market need internationally shared standards of competence if they are to be successful in driving the global economy. Hence, experts argue that it is time to consider the active role that international organizations are now playing, and being increasingly called on to play, in building a world educational culture, one in which all can fully and equally participate (Resnik, 2006).

Technological Education and International Organizations

The rhetoric promoting such an approach to education might sound like the previous call for education for all, but there are deep differences. The earlier call was driven by a normative sense of egalitarianism; the more recent call is, to a large extent, driven by economic considerations. Thus, for example, it is tempting to see current efforts at providing open source access to systems of knowledge as a move toward more equitable distribution of research and innovation opportunities. Nevertheless, such efforts could easily prove to be tied to more narrow national and international economic interests and competition, as we can see from the educational goals articulated by Vietnam and also in other countries around the globe. In India, for example, there is a rapidly growing system of Indian Institutes of Information Technology originally funded by the Ministry of Human Resources and Education and now increasingly through private and public partnerships. Twenty such institutes have already been established, and several more are envisioned.

Regardless of the efforts of individual countries, as already noted, international organizations promoting and supporting education in this globalized, neoliberal knowledge economy have come to operate as intergovernmental organizations, and become central actors in a globalizing world with demands for shared educational standards and results as well as governance. In addition, since they first arose, each international organization has developed its own history, organizational structure, and culture. Importantly, operating as independent organizations, they have come to develop and pursue their own interests and agendas and often stand accused of having lost sight of their original shared vision of creating global equity of opportunity through the development of social, cultural, scientific, and economic capacities in harmony with each other under the umbrella of large global organizations like the United Nations.

Furthermore, these initial normative commitments are often obscured by more recent demands placed on international organizations by the shifts in the global economic landscape, even though the placement of education predominantly in the service of economic development is not a new concern (Vaizey, 1967). Critics have often noted the growing participation of economists of education and international organizations in the diffusion and consolidation of education around the world. That said, what is different in today's neoliberal economy is the explicit justification that entrepreneurship, product development, and managerial efficiency with a focus on educational outcomes have come to provide for educational research and practice. Innovation, in addition to diffusion and consolidation, has become vital to the business of developing a world culture of education. Typically, it is international organizations that place this kind of demand on educational institutions at all levels of what is an increasingly overt international capitalist system. It is not surprising, then, to see fast-growing emphasis on educating for scientific and technological excellence at the secondary levels, and for business and technology at the university levels. Even the humanities are only considered valuable to the extent that they are in the service of technological advancement. Human values – humanism in the old-fashioned sense of the term – are almost completely ignored in the vision of a posthuman world that now drives much of contemporary global educational policy. In the introduction to a volume on higher education in South Africa, the novelist J.M. Coetzee (2013) cautions against the elision of the humanities specifically, and the retreat of nations as educational policy is increasingly driven by international organizations, like the World Bank, in the service of the global economy: "The response of the political class to the university's claim to a special status in relation to the polity has been crude but effectual: if the university, which, when the chips are down, is simply one among many players competing for public funds, really believes in the lofty ideals it proclaims, then it must show it is prepared to starve for its beliefs. I know of no case in which a university has taken up the challenge."

Moreover, in addition to social and critical literacy, this push for technological innovation and development ignores the educational charge of fostering social cohesion and concern for the disenfranchised while respecting individuality and cultural differences. Thus, the World Bank is often accused of promoting a clear agenda for higher education in the service of the global economy, leaving other organizations within the global educational structure to pay attention to heretofore overlooked global concerns like the need for deepening and promoting human rights education. Anna Russell (2010) paints a particularly poignant picture of the manner in which international organizations have only just started to engage with the human rights community. Using the right to water as a case study, she demonstrates the ways in which international organizations either conceived of development in complete isolation of human rights and human rights education – it was not seen as relevant to practice – or addressed these issues under vague and unenforceable terms like *nondiscrimination* and *tolerance*. Russell calls for international organizations to develop robust institutional structures that would allow for

cooperation among organizations in development, placing human rights at its heart.

Human rights education is only one of the normative demands placed on the international organizations responsible for developing a world educational culture. Educating for social cohesion and citizenship, both within nation-states and at the international level, is an equally important task that international organizations must take responsibility for as they play their role as agents of change through education in the international system. It was Frederic of Prussia who noted that "there are few lands in which all citizens have the same religion, and the question arises: is such unity to be forced or can one permit everyone to think according to his own views?"(cited in Heynman, 2003). The turn to tolerance suggested by the Enlightenment philosophers as a solution to be achieved through education is that much more important today as we seek to improve tolerance, cooperation, and harmony between nation-states and subnational populations within a dense and increasingly integrated and equitable international system. Such universalism, however, is not to be thought without the specificity of the histories and cultures of the nation-states in question and also those of the international organizations themselves. It is to be kept in mind that until quite recently education has for the most part been viewed traditionally as relevant to local culture and therefore subject to local control. Certainly, the educational landscape is changing as international organizations become agents in the service of neoliberal global policies and the knowledge economy. Educators and policy makers are increasingly being called on to establish a general research agenda "on the formulation and transmission of world-level educational ideals and prescriptions to individual countries" (McNeely, 1995).

Conclusion

In sum, international organizations are now considered important in developing a worldwide pattern of educational institutionalization. Mass education – hence the calls for diversity and inclusion in all educational institutions, but especially those of higher education – has now become the imaginary that drives much of educational policy in the discourses of international organizations as well as national and regional educational institutions. For educators it is important to emphasize that this not merely an economic imaginary but also a normative one and as such demands education as a mark of citizenship. It is fair to say, though, that the policies developed and promoted by international organizations are often prescribed without sufficient awareness of local cultures and national political demands that leave the policies to be adopted in name alone, without effective local implementation. Thus, for example, the new technologies allow teaching to large numbers across the globe – thus meeting the demands of equal access to knowledge – but could really only be effective for the most culturally thin content. Even if we are committed to building global capacity for the knowledge economy, we would still need to attend to local social, cultural, and historical conditions for such learning to be effective and the development and use of appropriately relevant innovations. It is important to note, however, that organizations like UNESCO are indeed actively involved in supporting local efforts at preserving not only concrete heritage sites around the world but also cultural sites of intangible heritage (Ruggles and Silverman, 2006). Above all, given growing democratic demands across the international system and despite economic instability, postcolonial conditions, and the declining significance of public education, international organizations will have to play an even more active role as vast populations of the planet still stand in need of education policies that would meet the challenge of ameliorating the conditions of persistent global poverty and addressing the looming threat of increasing climatic disasters.

International Social Problems: A Systems Perspective

Heather K Manion, Royal Roads University, Victoria, BC, Canada

Abstract

There is no shortage of international social problems facing us today. How problems are defined and addressed depends on their conceptualization and interaction with other parameters within a wider system. This article suggests a set of domains that are needed to help individuals, communities, and societies move from surviving to thriving and suggests that international social problems emerge when these elements are out of equilibrium. The article argues that new, more holistic solutions that harness and enhance innate strengths or assets can address complex international social problems.

What constitutes an international social problem depends on what is meant by 'international' and 'social problem,' who is defining it, and how they are theoretically or paradigmatically positioned. Global conversations are influencing how international social problems are understood and addressed. Given contemporary global interconnectedness, the growing population, and new communication tools available, there are more influential conversations than ever. This behooves social workers and other social change agents to recognize the inherent complexity of international social problems so that they can better utilize key international partners and hidden assets and design more impactful solutions with more sustainable change.

International social problems encompass a huge range of issues and this article can only touch on the breadth of topics. It begins with definitions, explores the various global drivers of social change, including globalization, looks at the biases through which international social problems are conceptualized and illustrates key examples. The article then investigates several contemporary attempts to solve international social problems and examines the international players involved in defining and addressing social problems, including social workers, and concludes with a glimpse of future possibilities.

Definitions and Key Concepts

International social problems are dynamic and relative. A social problem is an issue that arises from a conflictual interaction between individuals and their environment (social or natural, domestic or cross-boarder). In 2000, Khan and Dominelli (2000) noted how social workers were experiencing the impact of globalization and an internationalization of some social problems. Many social problems are first felt locally, but expand in size or across nations to become international issues or concerns. For example, people displaced by war and forced to migrate beyond their borders, face a new set of policies, social and cultural practices, and laws as they attempt to make new lives for themselves.

Whether a social problem is deemed domestic or international does not significantly change its definition. I argue that given the intensely interconnected way people, goods, services, and ideas interact across borders, all social problems have become internationalized to some degree, either in how globalization shapes the way they emerge at a local level or in how they are understood and addressed across time and space. For example, George and Page (2004) illustrate how a domestic social problem, i.e., family violence, has been impacted by globalization in several ways: increasing poverty and unemployment leading to a rise in family violence; facilitate processes that allow people to share information about family violence and mobilize action that impacts upon international and national policy agendas. Untangling how issues are connected internationally can be complex, as can mobilizing social action across cultures and jurisdictions. However, the ability to mobilize action across the globe offers the possibility of garnering broader momentum of support, more diverse information and expertise, and more innovative approaches (Leadbeater, 2008).

Globalization and Unequal Distribution of Wealth

No examination of international social problems would be complete without recognizing globalization as a dominant global force. The impact of globalization has meant that the professionals who work on preventing or tackling international social problems are increasingly interrelated and influenced by global events and conversations. "… The internationalization of social problems blurs boundaries between nation-states. Problems experienced by one individual or group in one country can require solutions that involve professionals everywhere" (Dominelli, 2010: p. 57). Dominelli proposes that just as the global village shrinks, multiple communities of practice are developing across regions, nations, communities coalescing around similar issues.

While arguably there has been an increase in consumer-based wealth and well-being in the world, the gap between the richest and the poorest has increased significantly since the 1970s (Schuerkens, 2010; Collier, 2007). This gap breeds social problems and civil unrest (including increased relative poverty, unemployment, crime, lower average rates of health, more disparate access to property and public services, and more fragile democracy). The global distribution of money is

well documented. Forty percent of the world's population controls only 5% of the world's wealth, while 20% of the world's richest individuals accumulate three quarters of the world's income (Muhr, 2011). Muhr suggests those in the middle feed the global economic beast and those at the end are irrelevant. Inequity breeds disadvantage. This is at the heart of most international social problems (George and Page, 2004).

Ways of Viewing International Social Problems

People build lenses as a way to make sense of the complex world. International social problems can be seen through various lenses: sociological theories, practice approaches, and political–philosophical stances. Lens-specific approaches can mark cross-disciplinary or cross-cultural work by impeding dialogue. Analyzing the lenses through which an individual or group understands an international social problem can help to identify and ameliorate understandings leading to better analysis of problems and potential solutions (see for instance Foucault, 1969). Sociology has been responsible for creating lenses and making them more transparent (e.g., Kendall, 2007). For example, an examination of international social problems could focus on either the individual's relationship to the problem or conversely the underlying structure that shapes the problem.

Mazur (2007) suggests social problems are built on unique histories and conflicts; rooted in individual contexts. Glyn et al. (1996: p. 3) defines social problems as "situations, policies, or trends that are (1) distressing or threatening to large numbers of people, (2) contrary to the mores (essential practices) or moral beliefs of the society, and (3) partly or wholly correctable through the actions of social groups." Alternatively Kendall (2007: p. 23) defines social problems as forging individual and social conditions or patterns of behavior that necessitate public concern or collective action to make change.

Bronfenbenner's ecological systems theory (1979) envisioned a series of nested systems. Although his theory was originally focused on children's development, within the context of international social problems I use it to refer to the microsystem (the system most close to the individual, e.g., the family, community, and services used); the mesosystem (the interplay between microsystems); and the macrosystem (societal norms and the systems that hold these).

A systems approach broadens one's perspective by helping to conceptualize complex interrelations across paradigms. Systems approaches were built from multiple disciplines and have been criticized for lacking a cohesive framework. However, they provide an opportunity for conceptualizing problems within the context of their history, setting and take into account inherent benefits, detriments, strengths, and assets. This holistic transdisciplinary approach promises a better understanding of how different components of a system interact, and helps develop more sophisticated solutions where both intended and unintended consequences can be better predicted.

Analytical lenses, cultural 'common sense' principles, and assumptions are weaknesses that need to be recognized and when necessary, counterbalanced or at least questioned when addressing international social problems. That many social problems persist is testament in part to the limitations of our analytical prowess.

Re-Envisioning International Social Problems

Globally there are a plethora of complex, interlinking, and overlapping social and environmental problems. As a result, people are increasingly working on clusters of factors influencing social problems rather than focusing on single issues. For example, providing access to health care for a refugee lowers their vulnerability across a range of factors unrelated to health. Individuals and groups with inherent or imposed vulnerabilities feel the impacts of international social problems more profoundly and in greater frequency than others do. Similarly social problems are manifested differently over the life span and across micro- and macro-levels.

International social problems can be clustered in many ways. For instance, Mkandawire (2006) suggests these global issues: poverty and underdevelopment, democratic transition and consolidation, and social protection and inclusion. Similarly, they could be grouped according to the 30 articles outlined in the United Nations Universal Declaration on Human Rights (1948). Alternatively, an individual approach could be used, such as Maslow's (1954) hierarchy of needs (i.e., physiological needs, safety needs, love and belonging, esteem, and self-actualization) or a human development approach, as proposed by Nussbaum (2006) (i.e., life bodily health, bodily integrity, senses, imagination and thought, emotions, practical reason, affiliation, other species, play and control over one's environment).

Any clustering has advantages and disadvantages. This section provides a taxonomy for international social problems using seven domains. Drawing on elements from the above, these seven interdependent domains include (1) prosperity and equality, (2) sustainable livelihoods, (3) people and power, (4) interpersonal relationships, (5) people and the environment, (6) health and well-being, and (7) people and knowledge. This taxonomy attempts to challenge traditional typologies of international social problems by articulating a strengths-based approach. Each domain is prefaced with a vision of an ideal before outlining how international social problems materialize when these domains are out of balance.

Prosperity and Equality: From Survival to Thriving

Vision: a society where all individuals and communities have equal access to items required to survive (i.e., basic needs) and thrive.

To survive, people need access to shelter and protection, sanitation, nutritional food and safe water, social inclusion, and basic health care. In order for people to thrive and live sustainably with dignity they additionally need education and knowledge, sustainable livelihoods, communication technologies, community support, and self-determination (see Maslow, 1954 or Nussbaum, 2006).

Internationally, human beings are not thriving, and nearly 1 billion people are barely surviving (Collier, 2007). Extreme poverty exists both in rural and urban areas. Economic or material poverty and inequality are the most commonly cited international social problems. George and Page (2004) argue that the processes of globalization have exasperated poverty and unemployment in many parts of the world. Gaps between the richest and the poorest can precipitate issues like civil unrest locally, nationally, and cross-nationally. Collier (2007) suggests that while most of the world has benefited from global economic prosperity, 1 billion of the world's poorest are extremely marginalized. They are localized in 58, mainly African, nations. Collier argues that they share the experience of civil war or ethnic violence, failed or corrupt states, lack of access to seaports and dependence on natural resource exports that cannot provide economic prosperity or stability.

Poverty can also be conceptualized as an 'access' problem. In this way poverty is more than an issue of economics. It encompasses access to environment, social interaction, healthy housing, and justice. Who has access is culturally variable, complex, and often illogical. As an example, natural disasters and war heighten vulnerability and highlight 'access' issues, not least because individuals are separated from their normal support mechanisms and infrastructure. Resulting problems may include food insecurity, famine (and mass migration), starvation, and long-term homelessness. Unequal access to resources is inextricably tied to many social problems outlined in the following domains.

Sustainable Livelihoods

Vision: sustainable livelihoods provide access to basic needs, the opportunity to thrive, alongside a sense of identity and belonging.

Sustainable livelihoods can provide sustenance, economic viability, a sense of identity, social status, and the means to produce and distribute resources and services. While livelihoods provide benefits to some, the societal system is rife with social problems, including lack of access to employment or sufficient employment, and exploitation. These issues are often felt intimately at the domestic level, and become international when workers need to move across nations and regions to survive and thrive.

Focusing on global employment, Schuerkens (2010) notes that a global decrease in union power has led to more instability for the workforce and greater chances of worker exploitation. Underemployment is also on the increase with more people in part-time and casual positions. Although for some, this may be a lifestyle choice for many it is not. Discrimination in employment remains entrenched. Women still earn less than men in most nations (Schuerkens, 2010).

The search for employment can spur international migration. For some it is a matter of survival for themselves and their families through remittances (Lyons et al., 2006). International mobility can be seen, for example, with Pasifika workers doing seasonal work in Australia and New Zealand, Latin Americans traveling up the coast of North and Central America following the harvests, domestic laborers, and nannies brought into the Middle East or Western Europe, or the miners and retail workers from China brought into Canada. Exploitation is a risk for some global migrants who lack full legal privileges, access to education and skills training, or a social safety net.

More extreme problems include people trafficking, for instance, people trafficked from Sri Lanka to Australia or from Western Africa to Western Europe or young girls trafficked for sexual exploitation from Eastern Europe to North America and Western Europe (Lyons et al., 2006). The risk of exploitation can come from both traffickers and employers when workers have no recourse to legal or social support.

People migrate through choice, necessity, or displacement. Risks of exploitation and insecurity are increased further by the circumstances causing migration, especially in the case of famine or war. International social problems incurred from mass migration impact both those migrating and those left behind. Where mass exoduses have occurred economic collapse often follows, for instance in the US cities where big industry have relocated internationally or in the environmental devastation left behind with the abandonment of massive refugee camps in West Africa. Conversely, population explosion in many global cities has meant a growth in the number and size of urban slums. These often have their own social problems linked to crumbling infrastructure and inadequate transportation (Mazur, 2007).

The choice (or lack thereof) to participate in the labor market is particularly pertinent at either end of the life span, and for those with impediments that curtail their participation. For children, the participation in labor is contentious. Western concepts of 'childhood' are not universal (Rock et al., 2012). Yet, Myers and Bourdillon (2012) suggest that efforts to eradicate child labor internationally have imposed Western ideals without understanding local contextual rationales for child labor. Some families, communities, and even children such as those living on the streets are reliant on children's labor input at home, in the field, or on the street. However, children lack a political voice making them more easily exploited, for example, in commercial child sexual exploitation, as child soldiers or land mine removers. More holistic systems analysis of child labor has sidestepped purely right/wrong arguments, and advocated for solutions that better understand local context and support whole communities through more flexible education approaches that utilize mentoring and apprenticeship models that combine education with humane treatment and skills development (Myers and Bourdillon, 2012).

People and Power

Vision: individuals and communities recognize their power, and use it for the betterment of all.

Kahane (2010), building on Paul Tillich's theories, suggests the fundamental dichotomous drives underlying all complex social problems are power (expressed as self-actualization) and love (expressed as drive to unity). He argues that international social problems are left unsolved because one drive is encouraged over the other; either love over power or power over love.

Terms like governance, leadership, and transparency permeate international development literature. They purportedly keep

power in check, especially expressed as 'power over.' These debates are designed to codify 'access to' principles, for example, in the forms of rights for woman, fertility, indigenous cultures, cultural minorities, children, migrant workers, and disabled people (e.g., Lyons et al., 2006; Hölsher, 2012).

Discordant power creates an environment for corruption and corruption hampers social development everywhere. Through transparency and accountability, citizen participation in decision making is sometimes seen as an antidote to power imbalance. However, "participation is still circumscribed to the spaces authorized by the powerful" (Mkandawire, 2006: p. 400). More inclusive ways to balance power at both local and international levels have to be found.

Interpersonal Relationships

Vision: an empathic society where people live in harmony with each other, respecting each other's similarities and differences.

Conflict can be related to access, equality, human rights, and discordant societal values and norms. Social problems related to conflict and discordance include interpersonal violence, family violence, child abuse, crime, mass violent crime, social injustice, strife, weapon trafficking, deadly combat, child soldiers, sexual violence, dehumanizing acts, and war (George and Page, 2004; Kendall, 2007; Schuerkens, 2010; Mazur, 2007; Glyn et al., 1996; Collier, 2007; Hölsher, 2012).

Neuroscience has illustrated that people quickly and unconsciously group others into ingroups (i.e., friends) and outgroups (i.e., foes). Rock (2009) suggests that the conceptual circuits used to interpret what is being said from a 'foe' leads to a greater chance of misunderstanding and misinterpretation and less empathy. This coalescing around group identity has caused many international ethnic conflicts (Mazur, 2007) where little empathetic response exists. Calloway-Thomas (2010: p. 7) suggests "[e]mpathy is the moral glue that holds civil society together; unless humans have robust habits of mind and reciprocal behaviour that lead to empathy, society as we know it will crumble."

Finding ways to ameliorate the ingroup/outgroup divide and foster empathic societies could help to reinvigorate community practice to tackle international social problems. That people are not continuously at war with their neighbors points to an innate human asset, namely that people generally appreciate each other's company.

People and the Environment

Vision: policies and practices that support people to live symbiotically with their environment.

Growing recognition exists that human activity is changing the planet at a systems level. People are now bombarded with a litany of global environmental impacts causing social problems, including pollution, natural resource degradation, loss of entire species of plants and animals, climate change, extreme weather events, effects from extractive industries, artificial disasters, famine, food insecurity, rising sea levels, and others. These profoundly impact social well-being and threaten to increase (Steffen, 2011).

People's relationship with the environment may increasingly impact a multitude of international social problems. As an example, food security illustrates a tangible global threat. For many, 'vulnerability' is manifested by living on marginal unproductive or unsafe land (whether rural or urban). Urban areas house the majority of the global population and the ability to ensure food is both produced and distributed to those areas is tenuous (George and Page, 2004).

Health and Well-Being

Vision: social policies and practices put people's physical, emotional, spiritual and cognitive health, and well-being at the center.

Numerous social problems are affiliated with health and well-being, including, communicable and noncommunicable diseases, mental illness, health care provisions, access to medicines, pandemics, hygiene, immunization, protection, happiness, and identity. The interplay between ill-health and poverty is complex and well documented (e.g., Collier, 2007; George and Page, 2004; Glyn et al., 1996; Mills and Shillcutt, 2004; Schuerkens, 2010).

International efforts have gone into tackling international health problems. Consequently, infant and child mortality rates and the burden of communicable diseases including HIV/AIDS and malaria have been lowered and life expectancy has drastically increased (Horton, 2012). However more can be done with concerted international effort. The most common causes of death include heart disease, stroke, and respiratory illnesses and the largest global risk factors include high blood pressure, tobacco, alcohol, and poor diet (Horton, 2012). The most commonly cited health issues within international development are tuberculosis, malaria, and AIDS (Mills and Shillcutt, 2004). Mills and Shillcutt suggest the significant direct and indirect impact of communicable diseases on families and societies globally through mortality, morbidity, fertility, and decreased intellectual capacity is significant.

Well-being is trickier to quantify, but attempts to introduce a happiness index and human development index have begun. These emphasize a broader set of indicators to measure well-being, such as a strong identity, access to and participation in art and culture, civic engagement, a sense of purpose and belonging, and a home. People's access to land rights, culture and heritage, individual and collective memories, and language is integral to their sense of identity and well-being (Berry, 2008). People have complex relationships with place (e.g., home) and their sense of belonging. Not having self-determination and sovereignty can undermine personal and collective identity and lead to significant international social problems, including armed conflict and civil war (Hölsher, 2012).

When well-being is negatively expressed it can lead to social problems including self-harm, suicide, substance abuse, gambling, and other addictions, with wider socio-environmental conditions compounding issues. These traditionally individual problems are increasingly international in

nature with the double drivers of globalization and propagation of social and traditional media that can promote or encourage risky behaviors (George and Page, 2004). Supporting initiatives, attitudes, and movements that foster a sense of belonging and community is fundamental to helping communities thrive.

People and Knowledge

Vision: social policies and practice support full access to, and recognition of, diverse cultural knowledge and a freely available education system that helps people flourish.

Codified as a basic right within the UN Universal Declaration of Human Rights, education has been thought of as a fundamental means of extricating people from poverty. Utilization of knowledge has changed with the development of the Internet and social media, making education more accessible to more people (for those with access to this technology).

Ownership and control of this information is increasingly discussed. Movement toward democratization of information is taking the form of shared software development, Wiki pages, knowledge banks, and increased access to school at all levels, subjects and language, including freely accessible courses from the world's best universities. While a digital divide still exists, effort has gone into making information communication technology more accessible and affordable, including in poorer nations.

This opens opportunities for dialogue on international social problems, as well as improved knowledge sharing and education across a range of subjects, such as literacy, numeracy, health promotion, and agricultural advancements (e.g., Leadbeater, 2008; Kahn, 2012; UN, 2012; Schuerkens, 2010). New avenues for redressing some international social issues may include social workers in southern Africa using online repositories like the Australian Domestic and Family Violence Clearinghouse to access examples of how to work with perpetrators of violence; or community workers in rural El Salvador opening an online dialogue with people at Kew Gardens in the UK about building seed banks; or social entrepreneurs in Chennai sharing resources with their counterparts in Toronto through Changemakers; or social work educators in Ethiopia sharing classroom discussions with students in Japan on the efficacy of antioppressive practice through LinkedIn (see Section Relevant Websites).

Access to knowledge is related to the concept of ownership and monetization of knowledge. Issues surrounding intellectual property rights still produce major social inequity (Manion, 2005). Food security, indigenous knowledge of medical plants, and artistic license are just some of the areas regularly debated. Hindering an individual's access to their own or indigenous knowledge, heritage, and language has profound implications on their well-being (Berry, 2008). Many international social innovations are emanating from ancient indigenous practices. This requires an improved way to honor, understand, and respect knowledge from a broader range of sources and epistemologies, and open the door to new possibilities (see Blackstock, 2010; Dominelli, 2012).

Reframing Questions and Seeking Solutions

Grappling with international social problems often begins with identifying problems, formulating possible interventions, testing, redrafting and implementing programs, and evaluating impact. Most international projects continue to rely on time-limited, project-based interventions that struggle to create enduring social change (Jaques and Vanbalkom, 2012: p. 413). Preventative measures are costly, but after-the-fact measures are more so (Kendall, 2007). Similarly micro-level solutions or individual solutions can benefit individuals with personal problems, but they ignore systemic issues. Mid-range attempts to solve social problems, including groups that help individuals cope with problems and grassroots groups that work for community-based change, often lack sustainability and struggle for larger scale change. Macro-solutions are particularly at risk of political interference and often lack acceptance or acknowledgment of individual circumstance, wisdom, or choice (Kendall, 2007).

At this unique point in history, where globalization has both exacerbated some international social problems and created new avenues for tackling them beyond the constraints of national and regional borders, there are both new challenges and opportunities for social workers at the micro-, meso-, and macro-levels (Dominelli, 2012). An alternative way for social workers to tackle these problems is to focus on what is needed to succeed and thrive within populations across national or regional borders before being hampered by the problem itself. For example, a maternity clinic was set up for young expectant mothers in Kenya (Acumen, 2013). Women had had poor experiences of the clinic and were not using it. They decided to focus on what the clinic would look like and how it would function, if it were to successfully attract patients. A success-focused approach allowed the health provider to explore a broader range of solutions. Design played an important role. Field trips with expectant mothers included visits to luxury hotel lobbies to distill what creates a welcoming environment. As a result of changes made to the clinic, women started using the service, thereby reducing infant mortality rates. Acumen's Human Centered Design model has been used successfully in many countries. This approach is akin to an asset or strength-based approach that allows participation and a wider array of possibilities because it focuses on solutions, not problems.

Strengths-based practice sidesteps fragmented problem solving and focuses on holistic approaches, which assume self-determination using strengths and assets (Saleebey, 1992). Saleebey (1992) proposed asking the miracle question, akin to asking what success looks like or what is needed to help individuals and societies thrive. I propose a macro-scale strengths-based miracle question. Outside the realm of social work, several multidisciplinary community workers are beginning to look at ways to solve entrenched (international) social and environmental problems. Examples of innovative and collaborative ways to tackle old problems are available on these Web sites: Charles Leadbeater, Acumen, Changemakers, WorldChanging Web sites.

The Actors

The direction of change is driven by those who define what international problems, or constellations of problems are important and which will be tackled. Recent history has shown that actors driving international development debates are predominantly located in the more economically developed countries. They include international agencies such as UN agencies, International Non-Government Organizations, World Bank, International Monetary Foundation, World Trade Organization, government foreign policy and foreign aid programmes, private foundations, and some consortia and university scholars. The constriction of power vested in a small number of bodies can itself be a social problem, requiring an international and institutional response. As an example Collier (2007) cynically argues that the decisions to fund or focus on one issue or region over another is less about choosing the issues where assistance is most needed, or where it potentially will make the biggest impact, but more spuriously by international consultants and organizations who act in their own self-interests or by public pressure based on the whims of concerned celebrities.

Macro-level attempts to solve social problems include special interest groups for political change and national and international social movements, including the UN as a major player. Although the UN plays a number of roles in tackling international social problems, its four main purposes are keeping peace; developing friendly relations among nations; helping nations work together to improve the lives of poor people, conquer hunger, disease, and illiteracy, and encourage rights and freedoms; and supporting nations to achieve these goals (http://www.un.org/en/aboutun/).

Two notable examples of macro-level global attempts at social policy include the Copenhagen Consensus and Millennium Development Goals (MDGs) (**Table 1**). The Copenhagen Consensus involved global economists prioritizing the global challenges that held the most promising opportunities in 2004. Their list included, in order: climate change, communicable diseases, conflicts and arms proliferation, access to education, financial insecurity, governance and corruption, malnutrition and hunger, migration, sanitation and access to clean water, subsidies, and trade barriers (Lomborg, 2004).

The MDGs are social and environmental aspirations set for 2015. Some targets have been met ahead of time, some are on track and many are unlikely to be met (see UN, 2012). MDGs represent the closest attempt the world has had to a universal set of ideals and an intentional means of actualizing change across a range of international social problems. The following Web site outlines the eight goals and tracks their achievement about progress in each region from 2012 (http://www.un.org/millenniumgoals/pdf/2012_Progress_E.pdf).

Role of Social Workers

In recent years social work has grown significantly and shifted into increasingly diverse areas of practice. Dominelli (2010: p. 4) suggests that social work has been shaped by globalization through globalization of the profession and rising demand for services, fiscal crisis between state and market, technological revolution, increase in disasters, commitment to human rights and social justice, influence of international social work organizations, and persistent optimism. The growing internationalization of social problems, the increase in social workers working in international organizations, and the increasing interrelatedness of localized practice, all lend themselves to supporting initiatives, processes, and activities that promote innovative social change. The International Federation of Social Workers (IFSW), the International Association of Schools of Social Work (IASSW), and the International Council on Social Welfare (ICSW) illustrated a commitment to this with the Global Agenda for Social Work and Social Development: Commitment to Action (2012). Specifically, between 2012 and 2022, these institutions are committed to promoting social and economic equalities, the dignity and worth of peoples, working toward environmental sustainability, and strengthening recognition of the importance of human relationships.

Looking to the Future

Old thinking will not produce new solutions. The way forward is to ask better questions and open dialogue with a diverse range of stakeholders with a vested interest in facilitating positive change. Block (2008) and Kahane (2010) both provide different, but powerful examples of how this has been done at local grassroots level with community members (Block) and at the geopolitical level between multinational actors looking to solve issues of food security (Kahane). The new approaches needed to solve long-standing issues will require citizens, social professionals, and power brokers working at the micro-, meso-, and macro-levels. Current conversations attest to the appetite for new approaches to complex social problems. Approaches, interventions, practices, and policies that promote positive change are varied, including movements toward global governance, convergence of priorities and sectors, investments in private–public partnerships, the spread of sharing networks, rise of social enterprises and entrepreneurs, increased calls for meaningful dialogue to solve tough problems, and increased peer-to-peer advocacy and action.

Social justice is at the heart of organizations and professionals mandated to help, but ensuring this value is integrated into international social policy is a mammoth task. Social problems require a systemic approach that combines sociological, economic, political, educational, and public health analysis and considerations. Scalable innovative solutions to complex social problems will emerge where there is a confluence of these aspects. A more balanced approach that integrates best practices, historical and local contexts and integrates the wisdom and ability to act inherent in micro- and macro-approaches could provide more impactful solutions. Fostering actions, interventions, policies, and practices that enhance people's ability to thrive in their environment and flourish in communities will provide a better foundation for an international society that bolsters human dignity and provides a place for everyone.

Table 1 Millennium development goals

Goal	*Target*	*Progress (according to UN, 2012)*
1. Eradicate extreme poverty and hunger	Reduce extreme poverty by half	"Extreme poverty falls in every region" (p. 6)
	Productive and decent employment	"Eastern Asia sets the pace for worldwide progress on working poverty" (p. 8)
	Reduce hunger by half	"The numbers of malnourished have stabilized since 1990" (p. 11)
2. Achieve universal primary education	Universal primary schooling	"Progress on primary school enrollment has slowed since 2004, even as countries with the toughest challenges have made large strides" (p. 16)
3. Promote gender equality and empower women	Equal girls' enrollment in primary school	"Parity is achieved in developing world primary schools, even though some regions lag behind" (p. 20)
	Women's share of paid employment	"Equal access to job opportunities remains a distant target for women in some regions … Women, more often than men, turn to the informal economy" (pp. 22–23)
	Women's equal representation in national parliaments	"Women continue to gain representation in parliaments, but the pace is slow" (p. 24)
4. Reduce child mortality	Reduce mortality of under – five-year olds by two-thirds	"Child mortality falls by more than one third, but progress is still too slow to reach the target" (p. 26)
5. Improve maternal health	Reduce maternal mortality by three quarters	"Maternal mortality has nearly halved since 1990, but levels are far removed from the 2015 target" (p. 30)
	Access to reproductive health	"Fewer teens are having children in most regions, but progress has slowed" (p. 34)
		"The unmet need for family planning remains persistently high in regions with low levels of contraceptive use" (p. 36)
		"Aid to reproductive health care and family planning remains low" (p. 37)
6. Combat HIV/AIDS, malaria and other diseases	Halt and begin to reverse the spread of HIV/AIDS	"New HIV infections continue to decline in the hardest-hit regions" (p. 38)
	Have halted by 2015 and begun to reverse the incidence of malaria and other major diseases	"Significant and durable progress against malaria is underway" (p. 42)
		"The tide has been turning in the spread of tuberculosis" (p. 44)
7. Ensure environmental sustainability	Integrate the principles of sustainable development into country policies and programmes and reverse the loss of environmental resources	"Forest area increase in Asia is helping to slow, but not reverse, global losses worldwide" (p. 46)
	Reduce biodiversity loss, achieving, by 2010, a significant reduction in the rate of loss	"Biodiversity is still being lost, even as more areas of the earth's surface are protected" (p. 49)
	Halve proportion of population without improved drinking water	"Halve proportion of population without improved drinking water" (p. 52)
	Halve proportion of population without sanitation	"Despite improvement in most of the developing regions, the MDG sanitation target is still out of reach" (p. 54)
	Improve the lives of slum dwellers	"Improvements in the lives of 200 million slum dwellers bring achievement of the MDG target, even as rapid urbanization swells the ranks of the urban poor" (p. 56)
8. Develop a global partnership for development		"Core development aid falls in real terms for the first time in more than a decade, as donor countries face fiscal constraints" (p. 58)
	Address the special needs of the least developed countries, landlocked countries, and small island developing states	"Aid dips as a share of total donor income, as well as for LDCs and sub-Saharan Africa" (p. 59)
	Develop further an open, rule-based, predictable, nondiscriminatory trading and financial system	"Trade rebounds after the crisis, with market access largely unimpaired" (p. 60)
	Deal comprehensively with developing countries' debt	"Interrupted in 2009, the downward trend of developing countries' debt-service ratios resumes" (p. 62)
	In cooperation with the private sector, make available the benefits of new technologies, especially information and communications	"The extraordinary rise in mobile cellular subscriptions continues in the developing world" (p. 63)

International Social Survey Programme

Tom W Smith, NORC at the University of Chicago, Chicago, IL, USA

Abstract

The International Social Survey Program (ISSP) studies societies in comparative and temporal perspective. Since its founding in 1984 by Australia, Germany, Great Britain, and the United States, the ISSP has grown to cover 49 countries. Substantive topics and specific measures are repeated at regular intervals and include such themes as the role of government, national identity, work orientation, and social inequality.

The International Social Survey Program (ISSP) is a continuing, annual program of cross-national collaboration. It brings together preexisting, social science projects and coordinates research goals, thereby adding a cross-national perspective to the separate, national studies. The comparative perspective is important because in a globalizing world more and more social processes are international and interconnected and by placing countries in cross-national perspective one can differentiate between country-specific patterns and more universal phenomena.

ISSP evolved from a bilateral collaboration between the Allgemeinen Bevolkerungsumfragen der Sozialwissenschaften (ALLBUS) of the Zentrum fuer Umfragen, Methoden, und Analysen (ZUMA), West Germany, and the General Social Survey (GSS) of the National Opinion Research Center (NORC), University of Chicago, in the United States. (ZUMA is now part of Gesellschaft Sozialwissenschaftlicher Infrastruktureinrichtungen (GESIS) – Leibniz Institute for the Social Sciences.) Both the ALLBUS and GSS are replicating, time-series studies. The ALLBUS has been conducted biennially since 1980 and the GSS 29 times since 1972. In 1982, GESIS and the NORC devoted a segment of the ALLBUS and GSS to shared questions on job values, important areas of life, abortion, and feminism. Again in 1984, collaboration was carried out, this time on class differences, equality, and the welfare state.

Meanwhile, in late 1983, the National Centre for Social Research (NCSR)(then known as Social and Community Planning Research), London, which was starting a social indicators series called the British Social Attitudes Survey (BSA) similar to the ALLBUS and GSS, secured funds from the Nuffield Foundation to further international collaboration. Representatives from GESIS, NORC, NCSR, and the Research School of Social Sciences, Australian National University, organized ISSP in June 1984 and agreed to (1) jointly develop topics dealing with important areas of social science, (2) field the studies as a 15-min supplement to the regular national surveys (or a special survey if necessary), (3) include an extensive common core of background variables, and (4) make the data available to the social science community as soon as possible.

To govern ISSP, Working Principles were adopted (www.issp.org). These expressed ISSP's basic goals and established the structure for achieving them. ISSP is a collegial and democratic organization. The core institution is the annual plenary meeting of member countries where all members have equal standing and decisions are made by either consensus or majority rule. ISSP is coordinated by a Secretariat. A country is elected as the Secretariat for a 3-year term and may serve two consecutive terms. Great Britain (1985–91) served first followed by Germany (1991–97), the United States (1997–2003), Norway (2003–09), and Israel (2009–15). A Standing Committee consisting of the Secretariat and five other countries directs ISSP between the plenary meetings. The other permanent committee is the Methodology Committee, which oversees and reviews all technical matters relating to the design and execution of ISSP surveys.

The Working Principles also outline the basic procedures for drafting studies such as the role of drafting groups and the general meeting and the timeline for developing topics and final questionnaires. Moreover, it indicates ISSP's commitment to high data quality and functional equivalence across countries and stipulates standards for conducting and documenting surveys. This is shown in particular by the establishment of study monitoring reports, which are compiled for each round and detail the methodology used in each survey. The initial team of ISSP researchers was small and involved people running similar programs in their respective countries and could easily conduct cross-national research without a formal compact. By creating the Working Principles and setting down the rules and procedures, the team established a mechanism for the expansion of ISSP from beyond a collegial coterie into a large, diverse, international collaboration of social science institutes.

Each research organization funds all of its own costs. There are no central funds. The merging of the data into a cross-national data set is performed by the GESIS Data Archive for the Social Sciences, University of Cologne, in collaboration with the Analisis Sociologicos, Economicos y Politicos in Madrid.

Since 1984, ISSP has grown to 49 nations, the founding four – Germany, the United States, Great Britain, and Australia – plus Austria, Ireland, Hungary, the Netherlands, Israel, Norway, the Philippines, New Zealand, Russia, Japan, Bulgaria, Canada, the Czech Republic, Slovenia, Poland, Sweden, Spain, Cyprus, France, Portugal, Slovakia, Latvia, Chile, Denmark, South Africa, Switzerland, Venezuela, Brazil, Belgium, Finland, Mexico, Taiwan, Korea, Uruguay, the Dominican Republic, Croatia, Turkey, China, Italy, Ukraine, Argentina, Estonia, Iceland, Palestine, and India. In addition, East Germany was added to the German sample upon reunification. Past participants not currently active include Bangladesh and Brazil. The affiliated organizations are listed in Table 1. Other nations have replicated particular studies

without joining ISSP: East Timor, Indonesia, Kenya, Singapore, Sri Lanka, and Tanzania.

The annual topics for ISSP are developed over several years by a drafting group and pretested in various countries. The annual plenary meeting of ISSP then adopts the final questionnaire. Methodologically, ISSP researchers especially concentrate on developing questions that (1) are meaningful and relevant across countries and (2) can be expressed in an equivalent manner in all relevant languages. The questionnaire is originally drafted in English and then translated to other languages using rigorous translation and comparability checking procedures.

The themes covered in ISSP studies and the nations collecting data are listed in Table 1. The first theme on the role of government covered attitudes toward (1) civil liberties, (2) education and parenting, (3) welfare and social equality, and (4) the economy. The second theme was on social networks and support system. It contained detailed behavioral reports on contacts with various friends and relatives and then a series of questions about where one would turn for help when faced with various situations such as financial need, minor illness, career advice, and emotional distress. The third study, on social equality, concerned beliefs about what factors affect one's chances for social mobility (e.g., parental status, education, contacts, race, etc.), explanations for inequality, assessments of social conflicts, and related questions. It also asked people to estimate the average earnings of various occupations (e.g., farm laborer and doctor) and what the average earnings of these occupations should be. The fourth study covered the impact on the family of the changing labor force participation of women. It included attitudes on marriage and cohabitation, divorce, children, and child care and special demographics on labor force status, child care, and earnings of husband and wife. The fifth study on orientations toward work dealt with motivations to work, desired characteristics of a job, problems relating to unemployment, satisfaction with one's own job (if employed), and working conditions (if employed).

The sixth study in 1990 repeats the role of government theme. By replicating substantial parts of earlier rounds (at least two-thirds), ISSP has not only a cross-national perspective, but also an over time perspective. One is not only able to compare nations and test whether similar social science models operate across societies, but also able to see if there are similar international trends and whether parallel models of societal change operate across nations.

The seventh study covers the impact of religious beliefs and behaviors on social, political, and moral attitudes. It includes questions on religious upbringing, current religious activities, traditional Christian beliefs, and existential beliefs. The nonreligious items concern topics such as personal morality, sex roles, crime and punishment, and abortion. The eighth study in 1992 replicates and extends the 1987 social equality study. The ninth study in 1993 is on the environment. It includes an environmental knowledge scale along with attitudinal and behavioral measures.

The 10th study in 1994 repeats the 1988 study on gender, family, and work. It also adds items on household division of labor, sexual harassment, and public policy regarding the family. The 11th study in 1995 was on national identity. It assesses nationalism and patriotism, localism and globalism, and diversity and immigration. The 12th study in 1996 was the second replication of role of government. The 13th study in 1997 was the first replication of the 1989 study on work orientations. The 14th study in 1998 was the first replication of the 1991 religion study. The 15th study in 1999 was the second replication of the social inequality study fielded in 1987 and 1992. The 16th study in 2000 was the first replication of the 1993 environment study. The 17th study in 2001 was related to, but not a strict replication of, the 1986 social relations and social support study. In 2002, the 18th study was the third fielding of the gender, family, and work study. In 2003, the 19th study was the first replication of the 1995 national identity study. In 2004, the 20th study was a new study on citizenship. In 2005, the 21st study was the second replication of the work orientation study. In 2006, the 22nd study was the third replication of the role of government study. In 2007, the 23rd study was a new study on leisure-time activities. In 2008, the 24th study was the second replication of the religion study. In 2009, the 25th study was the third replication of the social inequality study. In 2010, the 26th study was the second replication of the environment study. In 2011, the 27th study was on the new topic of health policy and in 2012, the 28th study was the fourth fielding of the gender, family, and work study. In 2013, the 29th study will be the third fielding of national identity; in 2014, the first replication of citizenship; and in 2015, the fourth fielding of work orientation.

As of 2012, data from the first 26 studies are available from the GESIS Archive and various national archives such as the UK Data Archive at the University of Essex and Interuniversity Consortium for Political and Social Research at the University of Michigan. The 2011 study on health policy and the other rounds will be released in 2013 and later rounds will be available as soon as the data can be processed.

Publications based on ISSP are listed in a bibliography available at www.issp.org. The 2012 edition lists over 5200 publications. In recent years, over 400 publications have been added annually.

There are 12 collections of ISSP research: (1) Roger Jowell, Sharon Witherspoon, and Lindsay Brook, eds., *British Social Attitudes: Special International Report*. (Aldershot: Gower, 1989); (2) J.W. Becker, James A. Davis, Peter Ester, and Peter P. Mohler, eds., *Attitudes to Inequality and the Role of Government*. (Rijswijk, The Netherlands: Sociaal en Cultureel Planbureau, 1990); (3) Roger Jowell, Lindsay Brook, and Lizanne Dowds, eds., *International Social Attitudes: The 10th BSA Report*. ISSP marks several important developments in the area of cross-national research. First, since the collaboration between organizations is not special or intermittent, but routine and continuing, this has resulted in an enormous amount of data being collected. From 1985 through 2010, ISSP conducted 644 national studies with 870 275 respondents. With more and more countries joining ISSP, this mass of data will continue to grow. Second, ISSP makes cross-national research a basic part of the national research agenda of each participating country. This means that cross-national research is a central and integral part of each country's research program and not a separate and occasional appendage. Third, by combining a cross-time with a cross-national perspective, two powerful research designs are utilized to study societal processes. This provides a solid basis for the scientific study of human society and the rigorous testing of theories concerning societal processes and development. Fourth, ISSP epitomizes the perspective that cross-national research should be collaborative. It is the opposite of the safari research tradition in which researchers in a single country or a small group selected a topic, designed an instrument, and then exported it to other countries. ISSP studies are developed and approved by the assembly of all member countries. As such, they reflect a collective, international point of view. ISSP follows the principles of inclusiveness and equality and also improves cross-national research by being more sensitive and responsive to all the societies being studied. Fifth, ISSP is democratic. ISSP is not run by a small cadre of principal investigators. Decisions are made by the collective membership at general meetings either via consensus or by majority rule following the one-country, one-vote principle. One might suppose that 40-some countries seated around a table and having serious scientific debates over the merits of topics and how to measure them would lead to chaos and gridlock, but in fact ISSP has operated smoothly and successfully produced annual studies for over a quarter century. Sixth, analysis is egalitarian and open to all. Once a merged data set is created, it is released to all and non-ISSP members have the same access as ISSP members do to the data. This greatly increases usage and advances social science research. Finally, ISSP has inspired and helped establish additional cross-national research such as the East Asian Social Survey and the European Social Survey. The later in particular has advanced cross-national research notably and helped establish new standards of excellence in comparative research (Jowell et al., 2007; Smith, 2007, 2010).

Cross-national survey research is central to advancing social science knowledge. As Durkheim (1938, p. 139) noted in 1895, "Comparative sociology is not a particular branch of sociology; it is sociology itself, in so far as it ceases to be purely descriptive and aspires to account for facts." And this of course applies to the social sciences as a whole. First, it recognizes that the cultures and countries of the world are increasingly interdependent and that many processes are essentially global rather than merely national. As the Working Group on the Outlook for Comparative International Social Science Research has noted, "A range of research previously conceived as 'domestic,' clearly needs to be reconceptualized in light of recent comparative/international findings." Unless a comparative perspective is adopted, "models and theories will continue to be 'domestic' while the phenomena being explained are clearly not" (Luce et al., 1989). Second, comparing countries is very useful since placing societies in perspective illuminates their social location and knowing a country's relative position is as important as its absolute attributes. As Butz and Torrey (2006) have observed, "international replication of national findings is critical for distinguishing between local and universal phenomena. The recent development of internationally harmonized, cross-sectional data sets has already demonstrated their potential." Finally, even when one's interest is purely monocultural, comparative data can be very valuable. For example, if one follows a societal trend in a single country, one is prone to seek country-specific explanations for the trend. But if one has cross-national data and finds that the trend is multinational, then one needs to seek a different and broader set of explanatory factors beyond events and developments in a single country.

ISSP assists the expansion of social-scientific knowledge by gathering data on important societal topics in comparative perspective. As House et al. (2004) note, "The globalization of survey research creates the opportunity for comparative and multilevel research on the grand scale of nations or societies. Adding comparative survey-based data to the analysis can yield more precise and reliable answers to questions of great scientific and social importance."

Abstract

This article presents an overview of definitions of international social work (ISW), current debates, and future course of ISW profession and teaching. After a brief introduction, Section What Is ISW?: The Debate presents the debate on what is ISW. Scholars have argued that social work is a contextual profession and hence international and global social work debates are vane. Section Internationalization of Social Work: Profession and Education further elaborates the debate on internationalizing social work profession and education. The following Sections International or Universal Social Work? and International but Not Global? present the discussions on quest for universalism and on global social work. Section Conclusion is a concluding one.

Introduction

The term international social work (ISW) was first used by George Warren in 1943, serving on the American President Truman's Presidential Advisory Committee on Political Refugees. Warren must have used this term to describe social work practice in agencies that were engaged in organized international efforts (Xu, 2006). During this time, the UN Relief and Rehabilitation Administration's (UNRRA) programs became a hub of ISW activities. The UNRRA's programs contributed to the spread of ISW, as well as ISW education (Healy, 2001). The UNRRA was an international relief agency, largely dominated by the United States but representing 44 nations. Founded in 1943, UNRRA became part of the United Nations in 1945, was especially active in 1945 and 1946, and largely shut down operations in 1947 and its functions were transferred to several UN agencies, including the International Refugee Organization and the World Health Organization. Much prior to this initiative one can note the historical events at the end of the nineteenth century like the Jane Addams's adaptation of practices from the British Settlement Movement and Toynbee Hall in London to create Hull House for poor people in Chicago, and during the same time the Charity Organization Societies and their growth both in the UK and the USA as the humble beginnings of the ISW.

What Is ISW?: The Debate

Periodic conceptual articles on ISW reveal a growing scholarly understanding of the concept. ISW is a complex concept that has been defined by scholars both from global north and south drawing on their both local and international work (Cox and Pawar, 2006; Lyons et al., 2006; Healy, 2001). Nevertheless, some authors express their disagreement and questioned whether social work can be truly international in nature given its diversity, irrelevance of western models, and its primary commitment to local issues (Gray, 2005; Drucker, 2003; Webb, 2003; George, 1999; Harris, 1990). These scholars have argued that social workers are asked to perform vastly different tasks in different countries and cultures. The methods and values of social workers in different countries or even communities in the same country (like India) can be quite diverse, complicated, and socially incongruent, considering or recognising the different set of social arrangements and values given the different globalization impacts on the local communities in an ever changing country situations. Gray and Webb critique that "Social work is no different now than it was in the last century as it spread from the west to the rest with its colonizing civilizing mission replacing local, Indigenous healing practices and communitarian values with psychologizing individualistic treatment regimes. Culturally relevant social work practice is by its very nature localized and 'indigenized.'" They also further argue that "Internationalizing processes tread on the toes of indigenization or the adaptation of western social work to local cultural contexts" (www.socmag.net/?p=56).

During the 1930s, entries titled 'International Social Work' appeared regularly in the *Social Work Yearbook* published in the USA by the Russell Sage Foundation. These early definitions were quite specific and comprehensive, and included practice across borders, international assistance, work through international bodies such as the International Labour Organization and the League of Nations, and the international exchange facilitated by world conferences in social work (Warren, 1939, cited from Healy and Thomas, 2007: p. 584).

Hokenstad et al. (1992) defined ISW from a broad perspective as a professional practice that crosses national boundaries, and relies on contacts and exchanges between countries. Over time, the term ISW also came to encompass domestic social work practice with immigrants and refugees (Sanders, 1984).

Lyons (1999), writing from England, agreed that ISW "is a nebulous concept, with elements of cross-national comparison and application of international perspectives to local practice, as well as participation in policy and practice activities which are more overtly cross-national or supra-national in character" (1999: p. 12). Lyons also suggests a distinctive field of ISW that includes cross-border practice and efforts to influence policy and practice at a supranational level. Similarly, Lyons et al. refer to "the idea of international social work as a perspective or specialist activity" (2006: p. 5).

Barker's (1999) "international social work is about using social work methods or personnel internationally; about social work cooperation between countries; and/or about transfer between countries of methods or knowledge about social work" (p. 250).

Healy (2001) defined ISW as "international professional action and the capacity for international action by the social work profession and its members"; arenas for action include international professional exchange, international practice and policy, and those aspects of local and domestic practice that 'transcend national boundaries' (p. 7). She does not view ISW practice as a field, but uses the term international action and makes the case that due to increased global interdependence, both local social workers and domestic human service agencies have greater opportunities and even a responsibility to engage in international activities (see also Healy, 1995).

Haug's (2005) critique of the Western-dominated discourse on ISW called for emphasis on human rights and social justice, 'guided by a clear vision of a more equitable global society.' Haug believes that "international social work includes any social work activity anywhere in the world, directed toward global social justice and human rights, in which local practice is dialectically linked to the global context" (2005: p. 133).

Mohan (2008) asserts that "international social work may be defined as a discursive discipline that employs the knowledge and tenets of social work practice in a diverse, dynamic and interdependent world" (2008: p. 13). He further argues that "international social work should be redefined as a professional discipline that promotes trans-national knowledge, studies and experiences to foster equality and justice as vehicles of international understanding, collaboration and collective human social development" (p. 19).

Lyngstad (2013) observes two possible reasons for the controversy or the debates in ISW: "The first has to do with the fact that the raison d'etre of social work is contextual; it is hard to imagine that good social work is possible without focusing on the local context. The second reason is related to the way we are using the concepts. Concepts such as ISW, comparative social work, contextual social work and internationalizing social work are often used in a helter-skelter manner, thus the discourse related to these issues is somewhat blurred since the concepts are being used in a disorderly way" (2013: p. 401).

It is evident from the above discussion that there is a 'plethora' of definitions about ISW. It is also clear that the interpretations of what is ISW, ranged from placements and work in other countries, to work in one's own country with service users originating from different parts of the world, to collaboration between countries and international organizations as well as a consideration of the impact of global developments on local situations (Hugman, 2010). Concepts such as cross-national, global, and ISW are often used interchangeably (Healy, 2008). Thus, the concept is used in a wide sense "as a broad, umbrella term referring to any aspect of social work involving two or more nations" (Healy, 1995: p. 442).

The notion/concept of ISW has evolved over a period of time from a simple activity to a transnational discipline. What is common in all of these definitions by various scholars is the influence of globalization, human rights violations, migration, poverty and disasters, and the urgent need for cross-cultural, cross-boarder, interprofessional action. These are some of the concepts central to ISW. This debate is very important to inward looking, self-criticizing social work profession to further grow and develop as a full profession in different parts of the world. This debate also reminds us that whether ISW as a concept still evolving or only revolving?

Internationalization of Social Work: Profession and Education

Internationalization is again a very broad term. Some relate to internationalization of the curriculum, student exchanges, faculty mobility programs, the student market, and employability in a globalized context. Internationalization of education especially higher education is a global trend and social work is not isolated to this process. Higher education today globally is a competitive industry and a common resource. Many countries see it as an engine of economic prosperity and an artifact of intellectual property and for some a subtle way of neocolonialism. So what is internationalization of social work? How is it happening? And what are the impacts?

In recent years, there has been an increased emphasis on the internationalization of the social work profession (Caragata and Sanchez, 2002; Johnson, 2004; Heron, 2005), even though the notion of internationalization and knowledge exchange has existed for decades (Lalayants et al., 2013). Nagy and Falk (2000) have stressed the interconnected nature of problems across the globe. There is an urgent need for thorough understanding of the consequences and solutions for addressing these global issues. Given this complexity, only competent, trained social workers with an international orientation can work effectively. Sanders and Pedersen (1984) further argued that an additional benefit of international education is creating opportunities to promote collaborative relationships in social work education, practice, and research.

Some scholars viewed the internationalization of social work is a positive and dynamic aspect of contemporary practice. However few others have argued that it is another form of Western dominance. Askeland and Payne (2006) have argued "internationalizing social work education creates a Western hegemony in disseminating knowledge." Dominelli (2012, 2009) states that internationalization refers to objectives, processes, practices, policies, challenges, and strategies that link the local with the global and vice versa. Internationalization may be beneficial or exploitative; its outcomes vary according to the values and aims of different institutions practicing it. She argues that internationalizing practices cross-national borders and may or may not respect locality-specific values, cultures, and perspectives.

Midgley (1997) calls internationalism as an ideology that focuses on processes of international collaboration to reduce ethnic tensions and share the commonalities of a global humanity. Hugman et al. (2010) explored varied ideas describing the concept of ISW. They looked at ISW from the idea of globalization, and discussed how ISW is figuratively embodied in migrations. To cite an example, Germany is the fifth largest international contributor to the UK social work workforce after Australia, USA, South Africa, and India (Hussein et al., 2011).

Akimoto (2008) states that the following are not necessarily ISW. They are: (1) practice or research on or in other countries, (2) joint work with practitioners or professors of other countries, (3) international comparative research and analysis, (4) assistance to the second and or third World and research on South–North relations, (5) cross-cultural social work, (6) devotion to ISW organizations, and (7) participation in an international conference. He concludes that the 'internationalization of social work' is *not* identical with ISW. He further presents that ISW is irreconcilable with egocentrism, ethnocentrism, and xenophobia, and unable to do without 'compound eyes' or eyes from the outside.

The Council on Social Work Education (CSWE) in the USA is very supportive of social work educators' activities in international policy development and advocacy and professional exchange. The CSWE standards call for the insertion of global and cross-cultural content in social work curricula (CSWE, 2008). This has placed a responsibility on social work educators who are now challenged to find ways to deliver such knowledge to their social work students through internationalizing their curricula and introducing relevant changes in coursework and the field practicum requirements (Wehbi, 2011). Similar emphasis can also be seen in the UK and other countries.

As a response to increased demand for social workers who are competent in cross-cultural practice, some universities/schools of social work (e.g., Umea University in Sweden, University of Michigan School of Social Work offers a certificate in Global Social Work) have started offering courses in Internationalization and Social Work or some others titled as ISW as part of their social work programs. This trend suggests that some schools of social work have recognized the need for internationalizing their curriculums, teaching methods with an objective that their graduates will be able to work both in home country and other countries. In turn, this trend has raised increased pedagogical demands for the social work educators in these institutions. Pedagogical tools like 'reverse mission,' cultural immersion, and use of self-reflective journaling and reflective writing, group dialogue are being used (see Furman et al., 2008; Kreitzer et al., 2012; Lalayants et al., 2013).

The past and ongoing social, political, economic, and cultural processes in the global northern and southern states have resulted into a diversity of social welfare systems and governance structures that lead to differences in how social workers are taught, trained, employed, organized, and regulated. There is also a need for further research and publication into the student choices, preferred learning styles when it comes to ISW content. The ongoing social work innovations and scholarship building across many schools of social work provide pathways to further strengthen internationalizing social work teaching, learning, and ultimately the profession (Nikku and Hatta, 2014).

International or Universal Social Work?

From the early humble beginnings of social work in the nineteenth century, war and developments in one country or area influenced developments in others. The first international activities being organized in the nineteenth century when representatives of public and private charities began to organize conferences to share their experiences and exchange information on successful methods of practice. Despite this history, ISW has been described as the youngest branch of social work (Friedlander and Apte, 1968).

As early as 1960s, Benjamin Goldman (1962) published in International Social Work journal on ISW as a professional function and called for the development of ISW as a fourth method, to complement community organization, group work, and casework. Xu (2006) comments that "it is noteworthy that almost 80 years after social work first 'went global,' international social work is still struggling to become a well recognized and permanent field of social work" (2006: p. 682).

Similarly, the quest for a 'universal social work' is seen in the efforts of global organizations like IASSW, ICSW, and IFSW. These organizations are in the forefront in organizing joint global social work and social work development conferences beginning 2010 in Hong Kong, 2012 in Stockholm, 2014 in Melbourne, and 2016 in South Korea. The quest was also evident from the revisions of Global Social Work definitions in 2000 and 2014. The endorsement of Global Standards of Social Work Education (first presented at the international social work conference held in Montpelier in 2002, they were adopted by the social work community in Adelaide in 2004, see Sewpaul and Jones, 2004) is another hallmark of this quest for universalism in social work (see Gray and Fook, 2004).

International but Not Global?

The phrase 'Think Globally and Act Locally' has also been used by many social workers in their day to day practice. Some scholars have argued that social work may be international but not global. Some have argued it is neither international nor global. Yet some other asked: Is there a global common core to social work?

Weiss (2005) carried out a cross-national comparative study that examined the commonalities and differences in professional ideology among social work graduates in 10 countries by studying their attitudes toward poverty and the goals of social work. The major finding is the substantial similarity in the students' professional ideology despite the different contexts of their professional socialization process. Students in all the countries attributed poverty to structural causes and supported the extension of state social welfare as a way of dealing with poverty. They expressed a large degree of support for individual well-being and social justice as major goals of social work. The similarities and differences reflect the interplay of centrifugal and centripetal forces that fashion the characteristics of global social work.

Influential ideas and scholarship on critical social work and human rights, which I believe are part of ISW, came from Asia especially from Australia (see Allan et al., 2003; Ife, 1997; Napier and Fook, 2000; Pease and Fook, 1999). Australia and Aotearoa-New Zealand remain the important centers of social work in Asia and the Pacific region, through ISW activities emanating from these centers, they have had an impact on

social work in the surrounding Asia-Pacific region and internationally (Gray and Agllias, 2013).

Criticizing international or global social work, Stephen Webb (2003) suggested that "…social work has at best a minimal role to play with any new global order, should such an order exist" (p. 191). He argues that the concept 'global social work' is problematic. His thesis, that the role of the nation state remains significant and that social work is still essentially a locally based activity, is one with which, in many respects, we concur. Webb's suggestion that extension of social work to the global level and talk of 'ISW' is essentially a thinly disguised form of intellectual or linguistic imperialism among the social professions is one to be taken seriously (Braye et al., 2004: p. 4).

Conclusion

To conclude, we come back to the question that is been asked in the beginning: What is ISW? Is 'ISW' the same thing as 'universal social work' or similar to global social work? The definition and nature of ISW, however, remains contested. The notion or the idea of 'ISW' is a concept that is defined by various scholars and practitioners depending on their location and ideology. Hence it focuses on social work which crosses national boundaries and the practice is evolving for sure. With the advancement of global technologies, increased mobility and use of Information and Communications Technologies (ICTs), and academic mobility and student international placements to name a few, ISW has the potential to become a legitimate method of social work both in the global south and north. To become so it warrants cross-cultural understanding and mutual agreement to address some of the old and emerging global issues. It actually has the power to balance the western hegemony or professional imperialism if any by recognizing the other partners are also equal and crucial to practice ISW.

International Social Work Student Exchanges

Rosemary J Link, Simpson College, Iowa, IA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article identifies the goals, orientation, planning, and outcomes of international social work student exchanges. It argues that cross-cultural communication is a key skill developed by an exchange. The value base proposed includes belief in global interdependence, a willingness to scrutinize the history of student national and cultural identity, and commitment to evaluation. The knowledge base includes human rights, the history of social and economic development, and models of assessment and social justice.

Introduction

In his address to the Council on Social Work Education (CSWE) in Washington, D.C. in 2012, Tiong Tan from Singapore, asked his listeners to realize that we have to'break the mold' (Tan, 2012). Tan referred to the history of the social work profession in the Western World as still focusing on micro-systems, casework and the client as victim or person caught up in pathological relationships. Although many of the audience were radical social workers and community organizers, it is difficult to refute this imagery of the West when so much agency and therapeutic work is based on individual interventions financed through health insurance or in some countries, departments of child protection or education.

In contrast to this individualized and as experienced in some countries, 'colonial' model, Dr Tan characterized Asian social work as focused on the wider community, where the individual sees herself/himself as part of a greater good and the individual is deemphasized. Part of the challenge lies in funding sources for the profession. The exchange of information across countries can alert us to opportunities and strategies developed by other systems to separate the principles and implementation of social work practice from purely fiscal control. One example of fiscal control in the US is the influence of insurance company administrators on which claims for healthcare are appropriate. Fiscal responsibility is a professional expectation. When caught up in familiar systems, professionals may miss the wider array of practice that comes with a global view. Student exchange in particular, is a way to escape narrow vision. The focus of this article is the learning that can happen when students are encouraged into exchanges and conversations with social work students, educators and professionals in countries and cultures other than their own. In addition to conceptual arguments, reference is made to the increase in efforts to assess the impact of programs through research and evaluation (Van Hoof and Verbeeten, 2005; Center for Global Education, 2011).

The following introduction gives the background to the goals of student international exchanges in social work. Then the article develops in four sections focusing first on theory, followed by practical aspects of exchange and analysis:

- Introduction of Concepts and Theoretical Frameworks for International Exchange
- The Practical Framework and Types of Exchange
- The Future and Assessment of Exchanges
- Summary and overview of the goals and results of exchanges.

This article recognizes that there is a place for both of the approaches to professional practice that Tan refers to, plus some combination of medical/therapeutic and community/social and economic development change models. The premise of international exchange is to broaden thinking and recognize that limiting intervention to one model or another is to underserve communities. The tension becomes how to change traditions and find compatible language to share plans for effective future international and global collaboration in a fast globalizing world. Compounding this East–West divide is the current demonizing, especially in the US but also in Europe, of China's fast industrial growth and dominant market position (Editor, Economist, December 2012). For example, it was part of the Republican platform in the US during their 2012 presidential election, to cast China in the negative light of cheap labor and exploitation. An alternative view sees a vast country with much work to do in terms of fair working conditions, catching up on the same cycles of industrial and postindustrial growth that countries of the West have passed through (Midgley, 2012). India and China, are two vast countries caught up in rates of growth that strain every aspect of life (Editor, Economist, December 2012).

Letting go of ingrained stereotyping is one of the key opportunities and challenges of student exchange. Thus the first goal of student exchange is to reach beyond the familiar and to be curious about new cultural norms and the second is to realize that appreciating the cultural traditions of another does not lessen one's personal identity. As a result of a formal exchange in China, student Cali Breese illustrates this goal:

> I was invited into Peace Corps service … I thought I was ready…but each day I felt challenged to understand the dialects, the culture, strange sounds and smells, different social rules …
>
> Cali Breese, excerpt from Link and Ramanathan, Rowman and Littlefield, 2011: p. 199

Communicating effectively across cultures rests on the exchange of ideas with humility and respect, where students are eager to learn new ideas, in the context of an explicit (third) goal to reach intercultural understanding. Beyond the frank interpretation of meaning – what is trash to one, is rubbish to another is treasure to yet others – is the task to be truly curious, without feelings of superiority. It means realizing that our sense of reality is just one perspective on a complex gathering of cultures that make up the kaleidoscope of the world. Carter and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28049-5

Qureshi (1995) define culture in a way that reflects this notion of variety and equal worth: "culture is a learned system of meaning and behaviors that is passed from one generation to the next" in a geographical setting. Similarly Razack (2002: p. 251) puts culture at the center of student exchange, where colonial and oppressive history is looked in the eye and students challenge themselves to trace their generational identity.

It follows, that the theory of student exchange also focuses on challenging the 'hindsight' and superior interpretations of social and economic development. First, second or third world concepts are replaced with the (fourth) goal of recognizing that every country is part of a development cycle and all have elements of learning and human insight to share and to benefit from. A fifth goal, integration of this recognition of our universal generational experience of social and economic development, leads to more open attitudes to learning, to future career choices that include international opportunities and relationships (Bess and Link, 2012). Without this internalized recognition, social workers are at risk of ignoring valuable international policy instruments and worse, exposing themselves to unethical or illegal practice, such as the inadequate documentation of international adoptions (Rotabi, 2012; Shukovsky, 2003). These goals build the theory of student exchange, which is still relatively new, but the practice of exchange goes back much further (Lager and Mathiesen, 2012).

Thus the goals of student international exchange are about more than acquiring new knowledge and skill – they depend on a willingness to study cultural efficacy and to reflect upon values awareness. Researcher Terry Cross (1986) proposes a values continuum in relation to prejudice and racism, which offers a useful theoretical framework in organizing curriculum for an exchange. This theory is applied in the following section.

Introduction of Concepts and Theoretical Frameworks for International Exchange

International exchange in the social work profession has been flourishing for at least 100 years:

> … from the days of Toynbee Hall, the Settlement House in London visited in 1904 by the US community organizer and peace activist Jane Addams, to the early days of the Tata Institute in Mumbai and its center for international visitors. A leap forward occurred at the 1928 International Social Work conference in Paris, when social work leaders, including Addams and Jebb called for increased professional opportunities to exchange ideas and practice, with a primary goal being to promote peace in the world
>
> Cacinovic in Healy & Link, 2012: p. 343

Peace in the world was an imperative following the devastation of the nineteenth century battles in Europe and South Africa including the Boer War which ushered in the twentieth century; and the First World War (1914–17) which provided the catalyst for international exchange. Then, after the Great Depression and the eruption of the Second World War (in Europe 1939–45), there was rapid expansion in international organizations, pulling East and West into dialogue. Most central to the new forums for exchange during the 1930s was the League of Nations, and after 1948 the United Nations. Another step was the Commonwealth Youth Exchange Council, established in Nairobi and London in 1965. However, the domination of the norms of colonial power slowed true exchange. This is illustrated in the context of language that perpetuated attitudes of, First, Second, and Third worlds, first used in economic and development sociology (Midgley, 2012).

In 2013, the numbering of worlds in terms of economic and political status has been abandoned and the scene may be set for more genuine exploration of cultural meaning and exchange. Instead of a WalMart US style organization expecting its staff to smile broadly at strangers and stay open on Sundays in Europe, corporations are learning the hard way how to be successful – by listening to local custom. The transnational corporation 'Dairy Queen (DQ)' set up store in Ljubljana in Slovenia, in a country that has the best ice-cream and gelato outside Italy. It should be no surprise that DQ soon left, having given scant attention to effective forms of cultural exchange and underappreciating what was already in existence (Link and Cacinovic, 2012). This failure of a company to respect local norms is an important lesson for social work students reflecting on their own cultural awareness and communication.

The theoretical frameworks that apply to this exploration of international exchanges are those of Norton and the 'Dual Perspective,' Cross's 'Cross Cultural Continuum' and Bosch's 'cultural efficacy.' In Cross's continuum, students share their ideas about culture and come to realize that 'I respect everyone, I treat everyone the same' translates to the limiting 'same as me' (Cross, T. 1986: p. 6). Norton prompts initial awareness of how a person has the advantage when they join a workplace or community that reflects many of the same cultural norms and patterns that someone is raised with and in particular seems to put newcomers, migrant workers or exchange students at a disadvantage (Norton, 1997). Assignments and orientation to student exchange can be organized in ways that infuse these theoretical frameworks and focus on values and styles of communication.

In organizing student exchanges it is widely recognized that for some students this is their first foray into new lands and cultures (Mathiesen and Lager, 2007). There is a natural ignorance which can be compounded by lack of realization of the layers of norms that we build over a lifetime (Cross, 1986: p. 6). Norton speaks of students who settle easily into higher education because the context is familiar. A student at the University of Ljubljana, who speaks Slovenian, has ties with Italy settles into class in Ljubljana more easily than the student from Croatia or Bosnia who speaks different languages or dialects, experiences life on the outside of the European Union and is still caught up in the tensions of war.

Henna John-Fisk is researching the resilience of children of prostitutes through an exchange in Mumbai, India (Henna Fisk, 2012: p. 147). Part of John-Fisk's data highlights the preference of the children interviewed, to stay with their mothers. The research reports that the children understood what was pressuring their parent into prostitution and wanted to stay with them. For a Western reader, ignorant of the cultural ties in Mumbai that take into account the community of prostitutes, the oppression of the control of prostitutes by male handlers, it is easy to be shocked at the idea of a child staying with her mother in such circumstances. This is the cultural norm and professional response, even though the women

involved are often controlled by exploitive and violent men. It can be argued that there is a secondary oppression by society's attitude to their capacity for mothering.

It is realized that student exchange is multilayered and the theoretical sources referenced here become key design elements for educators. Lager and Mathiesen have identified 10 'facilitating factors' which are a combination of theoretical and practical approaches to student exchange in the context of international field placements. Five of these are:

1. A communication feedback loop with supervisor, field liaison, and student with mutual evaluation and debriefing.
2. Contact should be maintained at the micro, mezzo, and macro with the host country.
3. The common ethical framework established by the principles established by the IFSW is adopted by all participants.
4. A reciprocal strengths-based approach for all parties is assumed.
5. Mutual goals (Lager and Mathiesen, 2012: p. 338).

These concepts for building international exchange lead directly into the practical planning, orientation, implementation, evaluation, synthesis, cycles of exchange. The concepts also emphasize the important of ongoing learning and the message to students that this is a journey to be continued when they return from their exchange with their new perspectives and learning.

Practical Frameworks and Types of Exchange

An underlying theme of this article is: how can international exchange transform later professional behavior. What are some of the goals and challenges that need to be addressed, what are the best practices in international student exchange and what variety of forms do they take. The increase in commitment to exchanges is facilitated by the fact that the core professional international organizations for social workers endorse exchange, including the International Association of Schools of Social Work.

In the second decade of the twenty-first century examples of international exchanges are expanding fast and include: the Singapore Institute of Management which has extensive ties and professional exchange with social work programs in China (Tan, 2012); Harvard University in the US, which expects all students to have passports and to travel. Most of the universities of the European Union participate in former European Community Action Scheme for the Mobility of Univesity Students (ERASMUS) and now Socrates and Tempus (since the end of the Soviet Union) exchange programs:

Celebrating its 25th anniversary in 2012, ERASMUS is the most successful student exchange program in the world. Each year, more than 230 000 students study abroad thanks to the Erasmus program. It also offers the opportunity for student placements in enterprises, university staff teaching and training, and it funds cooperation projects between higher education institutions across Europe (www.ec.europa.eu/education/lifelong-learning-programme/erasmus).

Schools in India, including the Tata Institute in Mumbai, have long-standing relationships with employers in the Western World, and participate in student field placement exchange and international conferences. The National University of Singapore has extensive ties with India and the International Association of Schools of Social Work has just published a report on the 'IASSW and Indonesian Social Work: Building Capacity Together' (www.iassw-aiets.org, 24.01.13). An outstanding feature of this growth is the recognition that international student exchange contributes to curriculum development for faculty as well as learning amongst students.

Table 1 demonstrates the widening goals of exchange.

International exchanges occur through a variety of formats including:

- physical two-way exchange between host and sending organizations (including field placements)
- interactive video exchange between classrooms in different countries
- instructional exchange online.

Asamoah (2003) speaks of the unbalanced approach to exchanges in the past, with schools in the Western World designing the goals and expecting those visited to grasp their curriculum design and expectations:

> Many of the early exchange models are most accurately described as one-way consultations without a true exchange component, and some models lacked cultural relevance and sensitivity…
> Asamoah 2003: p. 3

The first step in planning then is to review the goals of the exchange with potential partners and to design the curriculum

Table 1 Goals for exchange

- Identifying a variety of solutions to common problems, such as child abuse.
- Encouraging social work students to question their own sense of cultural identity and 'norms' so that they become more accepting and welcoming of others.
- Expanding the knowledge of a variety of countries amongst students so that they understand the original impetus for immigration.
- Developing a sense of the strength of the profession worldwide to foster collaboration, especially at borders and in questions of human rights such as international adoptions.
- Building a curriculum that is relevant beyond the local situation which recognizes issues that are common to social workers worldwide, such as access to health, healthy pregnancy, access to safe environments for vulnerable people including older people, people with disabilities and children.
- Sharing and expanding theory and practice, for example the work in Ljubljana to 'cocreate' solutions for families. This work builds on the idea of a 'fourth wave' in social work practice – the first being community work, the second clinical practice and the medical model, the third being psychosocial work with an understanding of the person in their environment and the fourth being the expectation of working alongside rather than ahead or above service users (Link and Cacinovic, 2012, in OUP Handbook).

in outcomes language, for example: as a result of this exchange students will be able to explain the reason for professional adherence worldwide to the Convention on the Rights of the Child. The most successful physical and practical exchanges seem to be those where the emphasis in on institutionalizing the planning so that it endures changes in personnel, while also emphasizing the importance of building true friendly relationships. Hokenstad (2003) describes the ongoing exchange between the Department of Social Work at Eotvos Lorand University (ELTE) in Budapest and the Mandel School of Applied Social Sciences at Case Western Reserve University (CWRU) in Cleveland. He identifies advanced planning, regular contact and faculty sharing of curriculum innovation. Similarly the University of Ljubljana, Slovenia has developed multiple exchanges with partners in Europe, including Barcelona and Finland as well as long-standing exchanges with North America. Such enduring exchanges require the following planning, orientation, implementation and evaluation phases:

- in depth planning for each stage;
- visits between leaders through interactive video or preferably in person, including to experience ahead of the students where possible, accommodations, food, access to water and travel arrangements;
- shared goals for orientation in advance of travel;
- readings recommended by host setting for each leg of the exchange;
- frank discussion of cultural expectations and norms;
- norms for travel (partners; avoiding clothing with national slogans; attention to nonverbal behavior; adherence of local laws, for example, in relation to alcohol use, gum chewing, spitting, sneezing); and
- review of evaluations for implementation of changes and improvements each time.

Such detailed planning also includes crisis management and strategies for student misadventure or ill health. During an exchange in Slovenia, which included brief field agency experiences, the group leader (Link) was telephoned with the news that 'Victoria has blown up.' While taking the fast train to investigate, the group leader was reviewing her conflict negotiation skills. On arrival, she found that language had intervened to send the wrong message: the student 'threw up.' Language, particularly when participants are under the impression that they share it, such as English, can lead to much misinterpretation and deserves attention (Moss, 1994).

Planning leads to the detailed 'orientation' and preparation for learning prior to travel. The nuts and bolts of successful exchanges are characterized with well-documented organization such as demonstrated the Center for Global Education. In their 25th anniversary book, they address the elements of their orientation that have evolved over the years:

> As educators, we see our role as one that engages students and participants in the world, facilitating critical analysis and reflection that leads to action. We believe that intercultural dialogue and collaboration with decision makers and historically disadvantaged urban and rural communities are a way of developing greater understanding of the power relations in the world.
>
> McBride, 2007: p. 2

Orientation takes many forms but essentially the goal is to engage students in the exchange prior to travel. Key elements include identifying the theoretical framework, such as a human rights perspective for a social work exchange between Slovenia and the US, or as above, a feminist perspective for a program of exchange with Mexico and Nicaragua. As discussed above, cultural awareness is both a goal and an activity for students as they begin to apply their theoretical learning. Lyons and Ramanathan (1999: pp.175–176) identify activities during orientation including:

- Beginning a journal.
- Small group discussion of advantages and disadvantages of undertaking an international field placement exchange.
- Write a paper for presentation about the country you will be going to. What are its main demographic, geographic, historic, economic, cultural and political characteristics?
- Using these discussions draw up a checklist and action plan for departure and arrival in a new country.

Clearly orientation also includes all the practical matters of organizing a group and these include: a sense of geography is essential so maps have to be studied and local conditions including weather and terrain; travel arrangements are made well in advance so that students have necessary visas and passports, health preparation and immunizations are scheduled, students practice social norms, such as greetings, supplies are planned including water purification tablets, warm clothing, travel, health and loss insurance, finance planning and access to necessary currency. Guidance on international exchange can be found in many locations including the US State Department country information, Lonely Planet Gravel Guides and the World Health Organization country updates (www.who.org).

This short article on international exchange will not dwell on the details of implementation other than to identify key elements as listed above and references and resources. It is etched on this writer's memory to instill travelers with a knowledge of their surroundings and the importance of knowing where they are on the globe. Flying has robbed students of the sense of geography and borders.

Similarly, regular processing of events as an exchange unfolds assists students to see the relevance of their learning to their own practice.

In a program with the Center for Global Education in Mexico, a group called 'Luce Y Libertad' agreed to publication of a case study as long as it was in both Spanish and English so that they could share it with their community. This exchange between students and the women's self-esteem project led to direct learning for the students. They participated in classes on organizing themselves as a food cooperative and took their learning back to the MidWest, US (Link and Ramanathan, 2011).

In addition to physical, face-to-face exchanges, there is increasing attention to interactive video exchange between different countries, sometimes in a dyad and sometimes expanding to a trio of relationships. In 2004, the University of Singapore agreed to participate in a video exchange with Augsburg College, Minneapolis in the US, sponsored by the State Department. The project was one of 10 interactive video programs offered during 2004 and 2005 and is available both

through US State Department records and narratives by the faculty and staff involved (Link/Bill, 2005).

The interactive video classroom involves similar cultural awareness, practical planning and thoughtful exchange of ideas concerning curriculum to the planning for a physical exchange. The most notable differences lie in the protocols that the students themselves develop that include ways of nonverbally taking turns to converse; greetings; use of language; attention to process (Link and Bill, 2005).

An extension of the use of technology in multiple forms, such as Skype, Facebook, Twitter, and all other social media, is the opportunity for students to connect with one another outside the virtual classroom, to study, to become friends and to share insights about their practice. Technology is racing ahead and the expectations of the twenty-first century workplace mean that students require experience and practical assistance with online learning. Many universities have courses completely online so that it is a natural form of exchange for students to find themselves in virtual classrooms with students across the globe. The distinction here is that the online course is content driven and disciplinary based, and does not address the issues of cultural exchange expected in the true formal international exchange courses.

Also, many schools are now involved in a US initiative begun at universities such as the Massachusetts Institutes of Technology and Harvard, termed 'Massively Open Online Courses' or MOOCs. These courses are offered free of charge, enroll hundreds of students and are taught by professors who offer certificates of completion. There is lively debate as to the disruption caused by MOOCs and the positive stimulus for administrators in Higher Education to think more creatively about open access for students of all income levels. It follows that as courses become available online worldwide, that education will become more widely accessed in a variety of countries. Although MOOCs have yet to spread to social work, they are on their way as a new form of exchange.

The Future and Assessment of Exchanges

While every exchange will have its own itinerary and level of involvement with local social workers and human service professionals, there are some universal aspects to endings and evaluation. As described by the Center for Global Education (CGE) all of their courses include oral and written evaluations and follow-up meetings at 're-entry' to home country (CGE, 2007). Similarly, one of the enduring features of the Slovenia-Midwest US exchange has been the thorough review of feedback so that learning is built-in to the next iteration of the exchange. For example, 1 year costs were reduced via less expensive accommodations in a hostel used by many travelers, but the location, noise levels, and general stress of the accommodation led to re-instating an earlier location.

Van Hoof and Verbeeten undertook a detailed research project, including but not focused on human service, surveying 1487 undergraduate students from a variety of countries who were incoming or US students outgoing on courses abroad. They achieved a 23.74% response rate and although a limitation lies in the focus on one large, public US university, the data is useful. For example, the reasons for international exchange and studying 'abroad' were:

1. it is a good opportunity to live in another culture;
2. it is a good opportunity to travel;
3. I liked the country my exchange program was located in…
4. and when it came to determining what it had meant to their personal development, the respondents were most enthusiastic: 67.7% considered it extremely relevant (Van Hoof and Verbeeten, 2005: p. 42).

One of the most vivid quotes occurs in the introduction to Van Hoof and Verbeeten's evaluation research. A student, Penny Barend, asked for water at the first supper with her 'host' family in Italy, only to be told: "Wine is for drinking, water is for washing" (Van Hoof and Verbeeten, 2005: p. 44).

In a study of exchanges, Vestal (1994) spoke of the 'promise of today' and the expectations of the next generation of students. It is nearly 20 years since Vestal foresaw the expansion in student interest and recognition of global interdependence (Vestal, 1994). Students are recognizing the ideas of Dower and Williams research, that national borders are now false limits on knowledge and research (Dower and Williams, 2002). The diseases such as severe acute respiratory syndrome (SARS) and acquired immunodeficiency syndrome (AIDS) cross all boundaries and natural disasters unite everyone on the plant in the need for emergency preparedness and collaboration. At this time the United Nations is the focus for international learning and the work of the UN in establishing policy frameworks for practice are bearing fruit. An example of this is a simple one: staff at the adolescent refuge in Celje, Slovenia, say that it is a natural part of their work to use the Convention on the Rights of the Child. This contrasts with students in the US who live in one of the last countries in the world that is yet to ratify the Convention on the Rights of the Child.

Conclusions

As stated earlier, an underlying theme of this entry is, how can international exchange transform later professional behavior? The examples cut across all forms of social work intervention. Some of the impact of exchange dialogue is highlighted in the example of the use of the UN Convention on the on the Rights of the Child. Another is the impact of the University of Mona, West Indies on practice with elders in Hartford, following the longstanding exchange with the University of Connecticut, School of Social Work Center for International Social Work. The social workers at the Seattle Adoption Agency may wish they had been more involved in formal social work exchange to avoid their malpractice (Shukovsky, 2003).

This narrative has identified at least four key goals for international exchanges:

- to reach beyond the familiar and find new ways of doing familiar things;
- to be curious about new cultural norms and in doing so to realize that appreciating the cultural traditions of another does not lessen one's personal identity;
- to communicate effectively across cultures and make new friends in distant places of the planet; and
- to expand innovations, effective strategies and implementation of international policy instruments in social work practice.

These are just examples of goals highlighting the need for expanded dialogue across cultures and regions of the world. The goals undergird the hard and detailed work of making practical arrangements, implementing and assessing courses.

Apparently there is much thinking to do if we are to understand one another better; thinking and talking and walking together. Student international exchanges represent a key step toward this talking with one another. If social work exchanges continue to build, the next generation will take the new 'Global Agenda' seriously. The Global Agenda combined the work of the International Federation of Social Workers (IFSW), the International Association of Schools of Social Work (IASSW), and the International Council on Social Welfare (ICSW) and was agreed at a conference in Hong Kong in March 2012 (IFSW, 2012). The agenda includes 'a set of objectives to meet our joint aspirations for social justice and social development' (IFSW, 2012). The Global Agenda expects students and educators, through their exchanges, to join in communicating and organizing in solidarity with social work practitioners across the world. To be effective as a profession in a globalizing world, we have to seize the moment and build international exchanges.

International Trade: Commercial Policy and Trade Negotiations

Andreas Dür, University of Salzburg, Salzburg, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Commercial policy has a strong negotiated component, with many international trade negotiations aiming at the liberalization of trade. Why do we see these trade negotiations, that is, why do countries even aim to liberalize trade? What explains whether countries engage in multilateral or bilateral and plurilateral negotiations? And how do countries negotiate over trade, that is, which role does power play and what explains the choice of bargaining strategy in commercial negotiations?

Commercial Policy

Most countries today are more open to international trade than ever before in their history. While trade flows were severely curtailed in the interwar period, since the end of World War II trade has grown substantively faster than world output. In 2011, therefore, world merchandise trade amounted to no less than US$18 trillion (World Trade Organization, 2013: 5). International trade no longer only concerns trade in goods; services trade, for example, the cross-border provision of financial services, also plays a crucial role in the expansion of trade. Moreover, countries trade an increasing amount of intermediary goods, leading to the establishment of global value chains and global production networks (Elms and Low, 2013). As a consequence, the world economy has become highly dependent on world trade.

The rapid growth in cross-border trade has been driven by technological innovations that have reduced the costs of trade. Not only have shipping and air travel become less expensive, but also the cross-border provision of services has become much easier as a result of the Digital Revolution. Next to technological changes, however, also the commercial policies adopted by countries across the globe have facilitated the growth in trade. Commercial policy is the part of government policy that directly aims at influencing the amount of trade that crosses borders. This can mean boosting trade, for example, by reducing barriers that hinder imports. Trade barriers include both tariffs and behind-the-border measures, such as discriminatory standards, that limit foreign imports. Boosting trade can also be achieved by facilitating or even subsidizing exports. Commercial policy can also be protectionist, that is, be aimed at reducing trade, by increasing trade barriers both at and behind the border.

Commercial policy involves unilateral trade policy measures, such as unilateral increases or reductions in tariffs. In the United States, for example, the Smoot Hawley Act (1932) unilaterally increased tariffs across most imports, leading to a substantial decline in foreign imports. More recently, many emerging economies unilaterally reduced their tariffs, with Chile a particularly prominent example (Edwards and Lederman, 1998). Some trade policy measures are also inherently unilateral. This is the case for antidumping actions and countervailing measures. The former are duties imposed when a country suspects that another country sells a product below the price of production. Countervailing measures are a response to subsidies given by another country. Because commercial policies do not only affect the own country but also trading partners, however, commercial policy also has a strong negotiated component. In fact, ever since countries engage in trade, they have signed agreements that facilitate or restrict trade between two or more countries.

Commercial policy measures can be applied preferentially or nonpreferentially. A tariff cut, for example, can be extended to only a few countries (for example, in form of a preferential trade agreement (PTA)) or to all countries benefitting from 'most-favored-nation' treatment. Most-favored-nation treatment means that a country receives at least the same if not more trade advantages than any other country. In the words of Jackson (1997: 160–161), it establishes "an obligation to activities of a particular foreign country or its citizens at least as favorably as it treats the activities of any other country." Antidumping duties or countervailing measures create preferential treatment, as they target specific suppliers or specific countries.

Overall, then, commercial policy measures can liberalize or protect a market; can be imposed unilaterally or be the result of negotiations; and can be applied preferentially or in a nonpreferential manner. **Table 1** summarizes these three dimensions that can be used to characterize commercial policy. It offers examples for seven of the eight possible types of commercial policy measures. The eighth – a negotiated, nonpreferential protectionist measure cannot be observed in practice.

Trade Negotiations as an Instrument of Commercial Policy

Trade negotiations are a key instrument of commercial policy. Most trade negotiations aim at the liberalization of trade, that is, the removal of trade barriers that hinder the flow of goods or services across borders. After World War II, 23 countries signed the General Agreement on Tariffs and Trade (GATT), which foresaw the stepwise liberalization of trade following the principle of reciprocity. Reciprocity means that countries exchange tariff concessions; one country agrees to reduce the tariff on a product in exchange for another country reducing the tariff on the same or another product. Establishing reciprocity, especially among many countries, required trade negotiations.

Table 1 A typology of trade policy measures

	Unilateral		*Negotiated*	
	Preferential	*Nonpreferential*	*Preferential*	*Nonpreferential*
Liberalizing	The unilateral removal of a specific trade barrier that only benefits one or a few countries	A tariff cut that is applied to all countries enjoying most-favored-nation treatment	A preferential trade agreement that liberalizes trade among two or a few countries	A trade agreement that leads to liberalization on a most-favored-nation basis
Protectionist	The imposition of antidumping duties that only affect one or a few countries	A tariff increase that is applied to all countries	A voluntary export restraint agreement	–

Note: the cell entries provide examples for the various measures. They do not represent a comprehensive list of trade policy measures.

Such trade rounds in the framework of the GATT took place in 1947, 1949, 1950–51, 1956, 1960–61, 1964–67, 1973–79, and 1986–93 (see **Table 2**).

The most important of these trade rounds, the Kennedy Round in the 1960s, the Tokyo Round in the 1970s, and the Uruguay Round in the 1980s and 1990s resulted in major tariff cuts and also the reduction of other barriers to trade (Cohn, 2002; Brown, 2003). The Uruguay Round also led to the creation of the World Trade Organization (WTO), which replaced the GATT in 1995. In the framework of the WTO, a major trade round – known as Doha Development Agenda – was started in 2001, with the negotiations still ongoing.

Trade negotiations also take place outside the GATT/WTO. Especially, the last two decades have seen the rapid spread of PTAs that are the result of negotiations between two or among a few countries (Mansfield and Milner, 1999; Dür et al., 2014). Examples are the North American Free Trade Agreement (signed in 1992), the agreement between Japan and Switzerland (signed in 2009), and the Australia-New Zealand Closer Economic Relations Trade Agreement (signed in 1983). At the time of writing, Australia, Chile, Japan, Mexico, the United States, and a series of other countries engage in negotiations for a Trans Pacific Partnership agreement and the United States and the European Union envisage the conclusion of a Transatlantic Trade and Investment Partnership.

Not all trade negotiations aim at liberalizing trade. Especially in the 1970s and 1980s, countries negotiated 'voluntary' export restraint agreements that restrict international trade (Bhagwati, 1988: 44). In these agreements, an exporting country agrees to reduce exports of a specific product to avoid the imposition of trade barriers by the importing country. A prominent example for a voluntary export restraint is the 1981 agreement by Japan to reduce exports of cars to the United States.

Why Do Countries Engage in Trade Negotiations to Liberalize Trade?

Trade negotiations thus mainly aim at the liberalization of international trade. But why are countries even interested in trade liberalization? It is generally agreed that free trade maximizes the welfare of all countries because it allows for goods and services to be produced in the most efficient locations. Free trade allows countries to specialize on producing the goods or providing the services for which they have a comparative advantage, meaning that they can produce or provide them at a lower opportunity cost than in another country. Countries thus do not need to have an absolute advantage in producing some goods or providing some services in order to benefit from trade; as long as countries differ in their relative efficiencies in producing different goods, all countries benefit from trade.

Trade, however, also has distributional effects (Alt and Gilligan, 1994). An expansion in trade redistributes wealth in a society, that is, it benefits some and hurts others. Two theorems offer contradictory predictions about who will win and who will lose from an expansion in trade. The Stolper–Samuelson theorem predicts that the relative price of the factor that is used most intensively in the production of

Table 2 Major multilateral trade negotiations

Name	*Time*	*Achievements*
Geneva	1947	Creation of the GATT and tariff reductions
Annecy	1949	Tariff reductions
Torquay	1950–51	Tariff reductions
Geneva II	1956	Tariff reductions
Dillon	1960–61	Tariff reductions
Kennedy	1964–67	Tariff reductions and an antidumping code
Tokyo	1973–79	Tariff reductions and several codes for nontariff barriers
Uruguay	1986–93	Tariff reductions, nontariff barriers, service liberalization, foreign direct investment protection, intellectual property rights protection. Creation of the WTO
Doha Development Agenda	2001–ongoing	The Bali package agreed upon in 2013 covers trade facilitation, food security, and preferential rules for least developed countries

a good will increase as production of the good expands. By contrast, the owners of the factor of production that is used less intensively in the production of this good will lose from an expansion of production. In a country exporting a labor-intensive good such as textiles, consequently, trade liberalization will result in an increase in wages. At the same time, the returns on capital will decline as the country increases its exports of textiles. This theorem builds on the assumption of perfect factor mobility, that is, it assumes that a factor of production can be moved without costs from one sector of production to another.

The Ricardo–Viner model, by contrast, assumes that factors of production are specific to a sector. This may be because the capital used in one sector is different from the capital used in another sector. For example, a cotton spinning machine cannot be used in the production of cars. Following this model, an expansion in exports of a good will increase the price of capital and labor employed in the specific sector; and decrease the price of capital and labor in other sectors. The expectation then is for capital owners and labor in exporting industries to favor trade liberalization, and capital owners and labor in import-competing industries to favor protectionist trade policies.

Several studies have tried to find out which of these two models better accounts for trade preferences (Magee et al., 1989; Rogowski, 1989; Hiscox, 2002). Magee et al. (1989) found support for the Ricardo–Viner model. At the same time, the Stolper–Samuelson theorem has been used to show that increases or decreases in trade, for example, those resulting from cheaper transportation, can have major political consequences (Rogowski, 1989). Socialism may have been a response to the expansion of trade in a backward economy with a low land-labor ration. West European Fascism may have resulted from a decline in trade in an advanced economy with a low land-labor ratio. Hiscox (2002), finally, showed that factor mobility varies over time; sometimes, then, the Stolper–Samuelson theorem applies and at other times the Ricardo–Viner model.

For many years, these distributional effects of trade have been used to explain countries' choices between protectionism and trade liberalization (Alt et al., 1996). The expectation has been for the losers from trade to push for protectionist trade policies; and the winners to support trade liberalization. Both the losers and the winners may create pressure groups that push for their respective stances by donating to decision makers, providing information or mobilizing the public. The political economy of trade then expects a government to take into account the relative strength of the two sides when designing its commercial policy. If factor mobility is high, the demands for protection or trade liberalization may also be reflected in party programs. In either case, the expectation is that whenever the protectionist side is stronger, the country will implement a protectionist trade policy; whenever the free trade side is stronger, the country will opt for trade liberalization.

Early on, however, scholars realized that the two sides in the trade policy debate may not be equally capable of getting organized and influencing government policy. In fact, traditionally the proponents of protectionist trade policies have been seen as having an advantage in mobilizing for political activity. The highly protectionist Smoot–Hawley Act that US Congress passed in 1932, for example, may have been the result of the highly effective mobilization of protectionist interests, whereas the free trade interests were all but absent from the political scene (Schattschneider, 1935). In this view, the benefits of protection are concentrated on a few producers, while the costs of protection are distributed among many consumers. Collective action problems (Olson, 1965) hence are seen as benefitting protectionist interests.

What then explains the move from protectionist trade policies to trade liberalization that we can observe just before and after World War II? Much research has focused on the passage of the Reciprocal Trade Agreements Act (RTAA, 1934) in the United States as the initial impetus for trade liberalization. The RTAA empowered the President to negotiate reciprocal trade agreements with trading partners. In a series of negotiations, the President used these powers to open foreign markets and bring down US trade barriers. For many, this piece of legislation, by shifting the responsibility for trade policy from Congress to the executive, allowed for the subsequent liberalization of trade (Lohmann and O'Halloran, 1994; Bailey et al., 1997; Gilligan, 1997). The institutional change may have been important because the President has a larger constituency than members of Congress and thus needs to take into account the negative externalities of protectionist policies for the welfare of the country as a whole (Lohmann and O'Halloran, 1994). The trade agreements that the president then negotiated with third countries locked in lower tariffs and made it more difficult for the at that time predominantly protectionist Republican Party to raise tariffs once back in control of Congress (Bailey et al., 1997). By concentrating the benefits of reciprocity on particular exporters, moreover, reciprocity created a powerful lobby for free trade (Gilligan, 1997).

These arguments, however, have not gone unchallenged. Referring to the RTAA as a 'magic bullet,' Hiscox (1999) argued that this account may explain what happened after the RTAA was passed, but cannot account for the passage of this piece of legislation. He argues that the act only passed because the back then free trade oriented Democratic Party controlled Congress at that time. The RTAA also did not lead to a stark reversal in the strength of protectionist and free trade interests in the United States in the following decades. Rather, for exogenous reasons, namely a shift in the geographic distribution of production in the United States, the Republican Party became increasingly divided with respect to trade policy. This allowed the RTAA to survive in the 1940s and 1950s even after the Republicans regained a majority in Congress.

The explanation provided in Dür (2010) also runs counter the institutionalist explanation. Here the argument is that twentieth-century trade liberalization was a response to the discrimination created first by the system of imperial preferences implemented by the United Kingdom and its dominions and then the process of European integration. Congress passed the RTAA only 2 years after the Ottawa agreements established the system of imperial preferences. Both societal interests and decision-makers supportive of the RTAA clearly alluded to the negative consequences of the Ottawa agreements for American exporters in making their case for the RTAA. Later, the creation of the European Economic Community in the late 1950s reinvigorated the American interest in trade liberalization, leading to the far-reaching trade liberalization agreed upon in the Kennedy Round. Most recently, following this account, the

discrimination created by the spread of PTAs propelled further trade liberalization.

Trade liberalization may also result from a change of ideas (Goldstein, 1993; Schonhardt-Bailey, 2006). In the nineteenth century, economic ideas may have played a major role in the British unilateral shift from protectionism to free trade, as exemplified by the repeal of the highly protectionist Corn Laws (Schonhardt-Bailey, 2006). More recently, the perception that the protectionist policies of the interwar period contributed to the Great Depression may have made decision-makers favor free trade policies. What is not completely clear from this explanation, however, is why most trade liberalization was achieved in international trade negotiations, rather than implemented unilaterally.

When Do Countries Engage in Multilateral and When in Bilateral or Plurilateral Trade Negotiations?

Commercial negotiations comprise only either two or a few countries (bilateral or plurilateral negotiations) or many countries (multilateral negotiations). The results achieved in trade negotiations, moreover, can be applied preferentially or on a most-favored nation basis. For many years, countries have been granting most-favored nation status to other countries (Horn and Mavroidis, 2001). Most-favored nation treatment also became a key element of the trading system that emerged after World War II. A key principle of the multilateral trade rounds taking place in the framework of the GATT/WTO is that any concessions offered by a country to another are extended to all members of the GATT/WTO.

At the same time, many bilateral or plurilateral trade negotiations aim at the establishment of PTAs that liberalize trade between two or among a few countries without extending these concessions to third countries. From a welfare perspective, under many circumstances PTAs are inefficient, as they may lead to the substitution of more efficient imports by less efficient production within the preferential trading zone. This effect is known as trade diversion (Viner, 1950). PTAs also create trade if inefficient domestic production is substituted by more efficient production from within the preferential trading area.

Despite their ambiguous welfare effects, PTAs have been mushrooming since around 1990. In the period from 1945 to 1990, countries around the world signed 208 PTAs (Dür et al., 2014). After 1991, this number substantially increased, with countries signing 525 new agreements between 1991 and 2009. Many of these new agreements not only reduce tariffs on goods, but also contain provisions regarding the liberalization of services trade, the protection of foreign direct investments, the harmonization of standards, and many other behind-the-border trade barriers.

Several explanations exist for why countries pursue preferential rather than multilateral trade agreements. For one, countries may find it easier to negotiate far-reaching agreements between two or among a few countries (Krugman, 1993). As of 2014, the WTO has 159 members. Agreeing on a multilateral agreement among so many countries has proven difficult. The Doha Development Agenda has been ongoing since 2001, with only limited results. In this view, PTAs simply satisfy countries' needs for negotiated trade liberalization in the absence of a multilateral agreement.

PTAs may not only be a second-best policy, however. Producers of goods that benefit from economies of scale may favor PTA because they allow them to increase their production and hence reduce unit costs without facing world-wide competition. A PTA then can serve as a springboard for these producers to achieve global competitiveness. Realizing this, these producers may lobby governments to sign preferential rather than or in advance of multilateral trade agreements (Chase, 2005).

Countries may also pursue PTAs for geopolitical reasons. A PTA may allow a dominant country to increase other countries' dependence on the own market, which in turn should increase the dominant country's power over these other countries (Hirschman, 1945). Similarly, a PTA may be an instrument to increase the military power of a set of countries. PTAs increase trade among the member countries; this trade creation enhances the national income of the participating countries, allowing them to invest more in defense (Gowa, 1994).

A PTA may also be a response to the PTAs signed by other countries. By liberalizing trade only among a few countries, PTAs discriminate against third countries. Exporters from these third countries suddenly find themselves in a situation in which they are no longer competitive in the PTA market, because they face higher trade barriers than firms inside the PTA. Third country exporters may then lobby their governments to also sign a PTA with the members of a PTA or to form a competitive PTA, leading to a domino effect that makes more and more countries sign PTAs (Baldwin, 1993; Dür, 2010; Baccini and Dür, 2012).

PTAs may also be a signal to voters in democracies that the government is pursuing efficient economic policies (Mansfield and Milner, 2012). The argument here is that voters often do not know whether an economic downturn is a result of the economic policies pursued by the government or exogenous circumstances. In doubt, they use elections to oust the government. Knowing this, the government can sign PTAs that signal to voters that it is pursuing an efficient economic policy, allowing it to stay in power even during economic downturns.

Finally, especially for governments in developing countries, PTAs may also serve to lock in domestic economic reforms (Whalley, 1998). Economic reforms can be painful; once implemented, they may not survive a change in government. By linking these reforms to better foreign market access in PTAs, governments can ensure the durability of these reforms.

How Do Countries Negotiate over Trade?

Early trade negotiations in the GATT were dominated by a few countries. Developing countries mainly were passive recipients of the concessions exchanged by the key trading nations. It was not before the Uruguay Round that developing countries became increasingly vocal. The increasing number of active players in multilateral negotiations has made the analysis of these negotiations substantially more demanding. Both multilateral and preferential trade negotiations have also become increasingly complex because of the growing number of topics covered in trade negotiations. Whereas originally the

negotiations mainly tackled tariff cuts, contemporary trade negotiations have a scope that goes far beyond tariffs and encompasses behind-the-border barriers to trade.

One important consequence of the increasing complexity of multilateral trade negotiations has been the emergence of coalitions that explicitly coordinate their position. In the Uruguay Round, for example, several coalitions of developing countries played an important role (Drahos, 2003; Narlikar, 2003). Bargaining together allowed them partly to balance the superior power of the developed countries. As preferential trade negotiations mainly do not allow for such coalition building, weaker countries may be more open to exploitation in these negotiations than in the GATT/WTO system.

An analysis of international trade negotiations thus always begs the question of who has power in these negotiations. There are several sources of power in trade negotiations (Drahos, 2003; Dür, 2010). A country's market size is key, as countries are more eager to get access to larger than to smaller markets. Access to the own market, then, can be 'sold' in exchange for concessions from the other countries. A country's domestic political institutions may also matter for the country's bargaining power in international trade negotiations. The literature on international negotiations shows that countries with high ratification requirements tend to be more powerful in international negotiations (Putnam, 1988). Finally, negotiation strategies may matter for a country's bargaining power. Choosing the right tactics at the right moment (for example, building a coalition) can give a country an advantage in the negotiations.

Existing research on the power of countries in international trade negotiations indeed provides evidence for power imbalances. Gruber (2000) showed that countries that are able to conclude trade negotiations without waiting for more protectionist countries possess what he calls 'go-it-alone-power.' This go-it-alone power allows them to impose certain trade policy choices on excluded countries. Kim (2010) argues that developed countries used their power to shape the multilateral trade institutions following their preferences. By doing so, they managed to affect trade flows in a way that benefit them to the detriment of developing countries. Dür (2010) argues that countries that discriminate against other countries manage to gain power in international trade negotiations. The creation of the European Economic Community, for example, enabled the European countries to extract concessions from the United States.

Some research has also looked at the strategies that countries use in international trade negotiations. Strategies are sets of tactics that countries adopt in pursuit of their objectives (Odell, 2006: 15). They vary between distributive and integrative bargaining (Walton and McKersie, 1965) or between hard and soft bargaining (Dür and Mateo, 2010). Distributive bargaining refers to a strategy that is aimed at claiming value from others. Integrative bargaining, by contrast, aims at creating value, that is, increasing the size of the pie that can be distributed in a negotiation. Hard bargaining refers to the use of conflictual or aggressive tactics; and soft bargaining to the use of cooperative or friendly ones.

A few studies report empirical evidence on the choice of strategies in international trade negotiations. Davis (2003) analyzed how countries use issue linkages to reach compromises in agricultural trade negotiations. Elms (2006) studied US strategies in negotiations with Japan and South Korea in the 1990s. She shows that countries adopt a distributive or value-claiming strategy when they face losses in trade negotiations. They do so even though a distributive strategy is likely to result in a suboptimal outcome.

Outlook

The increasing scope of international trade negotiations has made them increasingly salient to the public. The Seattle WTO Ministerial Meeting of 1999, which was supposed to start the multilateral trade negotiations later known as Doha Development Agenda, witnessed violent protests (Smith, 2001). The Anti-Counterfeiting Trade Agreement signed in 2011 and 2012 was not ratified by the European Union because of a massive mobilization of citizens opposing the transnational protection of intellectual property rights (Dür and Mateo, 2014). The negotiations for a Transatlantic Trade and Investment Partnership have also experienced a bumpy start after the plans for investor-state dispute settlement – namely the ability for private investors to sue states before an international tribunal – were publicly debated. While earlier trade negotiations were nearly exclusively decided by a few negotiators, this greater public salience will have a major effect on current and future trade negotiations. It will influence the speed of liberalization; countries' choice of multilateral or bilateral negotiations; and power and strategies in negotiations.

International Trade: Economic Integration

Anthony Venables, London School of Economics, London, UK

© 2001 Elsevier Ltd. All rights reserved.
This article is reproduced from the previous edition, volume 11, pp. 7843–7848, © 2001, Elsevier Ltd.

Abstract

Regional economic integration occurs when countries come together to form free trade areas or customs unions, offering members preferential trade access to each others' markets. The article reviews the economic effects of such agreements on member countries and on the world trading system. Effects on member countries include the benefits and costs of trade creation and trade diversion, as well as gains from increased scale and competition. 'Deeper' integration can be pursued by going beyond abolition of import tariffs and quotas, to further measures to remove market segmentation and promote integration. Effects on the world trading system are not clear-cut. There is little evidence that regionalism has retarded multilateral liberalization, but neither is there support for the view that continuing expansion of regional agreements will obviate the need for multilateral liberalization efforts.

Regional integration agreements (RIAs) are groupings of countries formed with the objective of reducing barriers to trade between members. They have long historical antecedents, sometimes being a stage to nation building (most famously in the Zollverein of nineteenth-century Germany), and sometimes as part of colonial trading arrangements. In the postwar period, developments were led by the European Union (EU, originally the European Economic Community (EEC), founded in 1958), and in the 1960s and 1970s there was a number of rather inward looking (and largely unsuccessful) RIAs between developing countries. Since the mid-1980s there has been a dramatic increase in regional integration activity. Of the 194 RIAs notified to the General Agreement on Trade and Tariffs/World Trade Organization (GATT/WTO) at the beginning of 1999, 87 were notifications since 1990. Now almost all countries are members of at least one RIA, and more than one third of world trade takes place within such agreements. The new developments include the expansion and deepening of the EU; the construction of new and more open RIAs between developing countries; and the advent of RIAs in which both high-income and developing countries are equal partners, lead by the North American Free Trade Area (NAFTA) which, in 1994, extended the Canadian–USA free trade agreement to Mexico.

RIAs come in many shapes and sizes. They vary in income levels, in openness to trade, and in the share of trade that takes place within the RIA, (60% for the 15 members of the EU, but just 10% for the eight members of the West African Economic and Monetary Union). Structures vary, from the loose agreements to facilitate trade of the African Cross-Border Initiative and Asia Pacific Economic Cooperation (APEC) forum, through to the deep integration of the EU, involving the construction of shared executive, judicial, and legislative institutions. The focus of this article, in common with most of the economics literature, is on RIAs as mechanisms for trade liberalization, not addressing the integration of factor markets, monetary systems, or political institutions. Even with this focus, RIAs differ widely in structure. 'Free trade areas' remove internal tariff and non-tariff barriers, but permit members to retain independent external tariff policies. 'Customs unions' go further, in fully harmonizing external trade policy. And it is increasingly recognized that effective integration of markets requires more than reducing tariffs and quotas. Many other barriers – such as differing national product standards and a host of minor border frictions – impede trade and support market segmentation, and some RIAs are now pursuing 'deep integration' policies to eliminate these barriers.

This article is organized under four main headings. Section Economic Effects on Member Countries outlines the main effects of RIAs on member countries, Section Policy Making discusses some of the wider policy choices faced in RIA formation, and Section Regional Integration Agreements and the World Trading System looks at the implications of RIAs for the world trading system as a whole. Section Conclusions concludes.

Economic Effects on Member Countries

Trade Creation and Diversion

The modern analysis of RIAs dates from Viner (1950), who drew the distinction between the trade creating and trade diverting effects of RIA formation. The classical source of gains from trade is that global free trade allows consumers and firms to purchase from the cheapest source of supply, hence ensuring that production is located according to comparative advantage. In contrast, trade barriers discriminate against foreign supply, inducing domestic import-competing producers to expand even though they have higher costs than imports. This in turn starves domestic export sectors of resources and causes them to be smaller than they otherwise would be. Since a RIA liberalizes trade, reducing at least some of the barriers, doesn't it follow that it too will generate gains from trade? Viner's contribution was to show that the answer is; not necessarily. The gains from trade argument applies if all trade barriers are reduced, but need not apply to a partial – and discriminatory – reduction in barriers, as in a RIA. This is because discrimination between sources of supply is not eliminated, it is just shifted. If partner country production displaces higher-cost domestic production then there will be gains – trade creation. But it is possible that partner country production may displace lower cost imports from the rest of the world, and this is welfare reducing trade diversion.

The analysis of trade creation and trade diversion constitutes one of the first formal analyses of the more general

 http://dx.doi.org/10.1016/B978-0-08-097086-8.71039-7

problem of 'second-best welfare economics.' Given that distortions remain in place in some activities in the economy, it is not necessarily the case that removing just some of the distortions (e.g., eliminating trade barriers on partner countries and leaving them in place on external countries) is welfare improving. In the literature on regional integration the response to the fundamental ambiguity created by the second best took three main forms.

First, authors established circumstances under which there is no interaction between formation of the RIA and external trade flows, so no possibility of trade diversion. Meade (1955) pointed out that if trade barriers with nonmembers take the form of fixed quantitative restrictions, then a RIA must raise the total welfare of member countries since there is no possibility that imports from the rest of the world are displaced. Ohyama (1972) and Kemp and Wan (1976) showed how, when external trade barriers take the form of tariffs, it is possible to adjust these to hold external trade volumes constant, so preventing trade diversion from occurring.

Second, researchers identified conditions, in terms of changes in endogenous variables, for welfare gain. For example, welfare increases if the initial-tariff weighted change in trade volume is positive (Meade, 1955). If internal tariffs are close to zero, then reducing them to zero raises welfare if it increases tariff revenues earned on external trade (Ethier and Horn, 1984).

The third approach is to identify features of economies (in terms of their underlying exogenous characteristics) under which they are more or less likely to gain or lose from RIA membership. Lipsey (1957) argued that joining with countries that are already one's largest trading partners is unlikely to lead to diversion, since the fact that the countries were originally the largest trading partners suggests that they are the lowest cost source of supply. Similar reasoning, including transport costs in the costs of supply, leads to the 'natural trading bloc' argument (Wonnacott and Lutz, 1989; Summers, 1991). Venables (2000) shows that those members of an RIA with comparative advantage most different from the world average are most likely to lose from trade diversion, as their trade is diverted to partner countries with comparative costs between theirs and the world average.

Empirical work on trade creation and trade diversion has taken two main forms; econometric studies of changes in trade flows, and computer simulation studies of the full general equilibrium effects of RIA membership.

Econometric studies seek to quantify the changes in trade flows attributable to membership of a RIA, and thereby identify trade creation and diversion. A variety of different econometric models have been developed, the most common being based on the gravity model which estimates bilateral trade between countries as a function of their GDPs, populations, the distance between them, and physical factors such as sharing a land border, and being landlocked or an island. Dummy variables capture whether or not countries are in a particular RIA, their estimated effect indicating whether countries in a RIA trade more or less than would otherwise be expected. Using this technique, Bayoumi and Eichengreen (1997) find that the formation of the EEC reduced the annual growth of member trade with other industrial countries by 1.7% points, with the major attenuation occurring over 1959–61, just as trade preferences were phased in. Soloaga and Winters (1999) look at a wide range of RIAs, producing a mixed picture with little evidence of widespread trade diversion. Overall, there appears to be weak evidence that external trade is smaller than it otherwise might have been in at least some of the blocs that have been researched, but the picture is sufficiently mixed that it is not possible to conclude that trade diversion has been a major problem. Furthermore, it cannot be inferred that trade diversion has been economically damaging without information on relative costs and tariff structures, variables that are not revealed in this sort of aggregate exercise.

The second empirical approach is based on computable equilibrium modeling. This involves construction of a full computer model of the economies under study and use of the model to simulate the effects of the policy changes associated with the RIA. Such a model typically contains a great deal of microeconomic detail, so can be used to predict changes in production in each sector, and changes in factor prices and real incomes. In models that assume a perfectly competitive environment, the combined effects of trade diversion and trade creation typically give very small welfare gains – just a fraction of 1% of GDP (see Baldwin and Venables, 1997 for a survey). The strength of these models is that they have sufficient microeconomic structure for the effects of a policy change to be traced out in detail, and its real income effects to be calculated. They are also often used for prediction – to estimate the likely effects of a policy change before it is implemented. But they have the major weakness that they are not usually fitted to data as carefully, or subject to the same statistical testing, as econometric models. The cost of the microeconomic detail is a complexity that makes rigorous econometric estimation impossible.

Although the focus of the trade creation and diversion literature has been on the changes in trade flows induced by regional integration, two consequent effects are important. First, changes in trade flows may change world prices, possibly improving the terms of trade of member countries, although this gain arises at the expense of outside countries. For example, if trade diversion occurs then RIA imports from outside countries are reduced, and any reduction in import prices that this causes is a terms of trade gain. Empirical work on this issue by Winters and Chang (2000) shows that Brazil's membership in Mercosur has been accompanied by a significant decline in the relative prices of imports from nonmember countries.

Second, changes in tariffs and trade volumes will lead to loss of government tariff revenue. This can occur directly (as intra-RIA tariffs are cut) and as a consequence of trade diversion (as imports are diverted away from external, tariff inclusive, sources of supply). Its cost depends on the social cost of raising funds by alternative means, and can be severe in some developing countries. For example, in the South African Development Community, where some countries are quite heavily dependent on trade with South Africa, substantial amounts of revenue are involved, amounting to perhaps 5.6 and 9.8% of government revenue for Zambia and Zimbabwe respectively. Cambodia derived 56% of its total tax revenues from customs duties prior to its entry into the Association of South East Asian Nations (ASEAN), and Fukase and Martin (1999) argue that

entry into ASEAN provided a powerful stimulus for the introduction of a value-added tax.

Scale and Competition Effects

A second mechanism through which member countries are affected by RIA membership derives from the fact that countries may be too small to support, separately, activities that are subject to large economies of scale. Regional cooperation offers a route to overcome the disadvantages of smallness, by pooling resources or combining markets. These scale benefits can arise in public projects (see World Bank, 2000) and also at the level of the private firm, where they typically interact with imperfectly competitive market structures. These considerations are absent from the trade creation and trade diversion approach outlined above, which is based on the perfect competition and constant returns to scale paradigm of traditional trade theory. It was only in the 1970s and 1980s that formal analysis of the interaction between trade, economies of scale, and imperfect competition began with the 'new trade theory,' and these techniques have now been extensively applied to regional integration.

The basic argument is that there is a trade-off between the extent to which firms can achieve economies of scale, and the intensity of competition in the market. For a given size market, larger firms means fewer firms and hence more monopolistic outcomes. If regional integration combines markets, then it shifts this trade-off, potentially allowing firms to be bigger and markets to be more competitive (Smith and Venables, 1988). For example, there might be an initial situation in which two economies each have two firms in a particular industry, and these firms exploit their 'duopoly' power, setting prices well above marginal cost. After formation of the RIA this becomes four firms in one combined RIA market. This increases the intensity of competition, and possibly induces merger (or bankruptcy), perhaps leaving only the three most efficient firms. The net effect is increased competition, increased firm scale, and lower costs. 'Triopoly' competition is likely to be more intense than the original duopolies, and surviving firms are larger and more efficient, so can better exploit economies of scale. A further source of gains comes from possible reductions in internal inefficiencies that firms are induced to make. If the RIA increases the intensity of competition, it may induce firms to eliminate internal inefficiencies (X-inefficiency) and raise productivity. Since competition raises the probability of bankruptcy and hence layoffs, it also generates stronger incentives for workers to improve productivity, and increases labor turnover across firms within sectors. Although these are significant potential sources of gain, they have been difficult to achieve in many RIAs. This is addressed further in Section The Depth of Integration.

Winners and Losers

A continuing concern is with the distribution of the costs and benefits of regional integration between member countries. Do central regions gain at the expense of peripheral ones, and do poor countries tend to catch up or get left behind? The evidence is, broadly, that RIAs composed of developed countries tend to show convergence (for example, the narrowing of per capita income differentials observed in the EU, see Ben-David, 1993). However, the picture for RIAs composed of developing countries is more mixed, with some examples of divergent performance (World Bank, 2000).

The analytical literature on these questions is quite sparse, but provides several clues why this might occur. First, as mentioned above, trade diversion is more likely for countries with 'extreme' comparative advantage, suggesting that in a RIA among developing countries it might be the lowest income countries that experience diversion. For example, their imports of manufactures might be diverted from nonmember countries to a partner that has a comparative advantage in manufactures within the RIA, but not relative to the world at large. Second, industries might tend to cluster in locations that have relatively good market access, or that are well supplied with business services or provision of other intermediate goods. This is more likely to occur in developing countries than in developed ones, partly because of their sparser provision of business infrastructure, and partly because the small size of their manufacturing sectors means that clustering is less likely to run into congestion and other sources of diminishing returns. The clustering may lead to wages being bid up in one member country at the expense of others.

Policy Making

The Depth of Integration

The simplest form of regional integration is the elimination of tariffs (or quotas) between member countries. Beyond this there is a wide range of policy options open to countries considering integration, many of which turn on the 'depth' of integration sought by member countries – ranging from modest trade liberalization, through full economic integration, to the formation of shared institutions.

The distinction between a free trade area and a customs union, in which a common external tariff is set, has already been made. The latter involves greater sharing of sovereignty and requires establishing procedures for revenue sharing, but in return can yield much greater market integration. In a free trade area where countries set different external tariffs the free internal circulation of goods is impossible; border formalities have to be maintained to ensure that external imports do not all enter through the member with the lowest external tariff, for re-export to other member countries. Since these imports include intermediate goods that are further processed in member countries, in practice this involves enforcing complicated 'rules of origin' governing trade flows within the RIA. (The EU's agreement with Poland has 81 pages of small print in its rules of origin section, and NAFTA some 200, Krueger, 1997.) These rules are not necessary in a customs union, enabling simplification – or elimination – of internal border formalities.

It is increasingly recognized that tariffs and quotas alone may be just a small part of the overall barriers to trade created by an international border. Rules of origin create frictions, and so too does contingent protection (such as antidumping rules, known to have a 'trade chilling' effect even when not used), duplicative customs procedures, differing national product standards, and simple border red tape. The cost of border formalities on intra-EU trade in the early 1990s has been

estimated to be more than 1% of the gross value of internal trade, despite implementation of procedures to cut these costs; in many RIAs the costs of border formalities are much larger.

Furthermore, relatively minor border frictions may constitute large real trade barriers because it can be in the interests of firms to try and limit effective cross-border competition in order to maintain collusive market-sharing arrangements. This will prevent the 'scale and competition' effects discussed in Section Scale and Competition Effects from being achieved.

Recognition of the importance of these barriers – and of the failure of more than 25 years tariff-free trade to truly integrate markets – was a motivation behind the 'deep integration' of the EU's 1992 Single Market Program (Flam, 1992). The program involved adoption of almost 300 measures falling into the following five main types.

1. Simplification and in some cases abolition of intra-EC border controls, involving, e.g., replacing border paperwork by an EU-wide system of administering value added tax on cross-border transactions.
2. Adoption of the 'mutual recognition' principle for product standards, under which a product that can be legally sold in any EU country can be legally sold in all, thereby removing the need for expensive re-testing and re-certification of products.
3. Progress towards deregulation of the transport sectors of EU countries, including measures to reduce restrictions on truckers from one country accepting loads in another.
4. Opening of public procurement in EU countries to effective competition from suppliers in all EU countries.
5. Deregulation of service sector activities, including opening financial services to competition and giving service providers and professionals the right of establishment in other EU countries.

Estimates of the gains from these measures range up to as much as 5% of EU GPD, although these are based largely on computable equilibrium studies rather than an actual survey of outcomes (see Baldwin and Venables, 1997).

Policy Reform and Commitment

Trade policy reforms – and other sorts of reform – are often hampered by the expectation that they may be reversed. Adjusting to reform typically involves investments, but these investments will not be made unless investors are confident that the reform will persist. These problems are mitigated if a country has a 'commitment mechanism' guaranteeing that the reform will be durable, and membership of a RIA can, in some circumstances, provide such a mechanism (Fernandez and Portes, 1998).

The commitment mechanism operates most obviously for trade policy – membership requires that tariffs with member countries be cut, and reneging on agreed internal liberalization is likely to bring swift retaliation by partner countries. However, it has been argued that RIAs are valuable as commitment mechanisms for a much wider range of measures. Although NAFTA was ostensibly about trade policy, an important part of its motivation was the desire on the part of both the Mexican and US governments to lock in the broad range of economic reforms that the Mexican government had undertaken in the preceding years. The EU Articles of Agreement with eastern European accession candidates are explicit in promoting 'full integration into the community of democratic nations.' And the intervention of other Mercosur countries is credited with having averted a military coup in Paraguay in 1996 (Survey on Mercosur, *The Economist*, 12 October 1996). Paradoxically, it is even suggested that the value of a RIA as a commitment mechanism is greatest in areas other than trade policy, because there is already a way committing to tariff reductions – the tariff bindings of the GATT/WTO.

Regional Integration Agreements and the World Trading System

The effect of regionalism on the world trading system as a whole has been the subject of extensive recent debate. Is the growth of regionalism part of a process towards global free trade, or is it a substitute for it, damaging to multilateral negotiations and likely to lead to a situation of protected trading blocs? It is noteworthy that RIAs go against the fundamental principle of the GATT/WTO, the 'most favored nation' principle under which trade policy must be non-discriminatory. They are permitted only via Article XXIV of the GATT, which requires that they cover 'substantially all trade' of member countries and lead to external tariffs that 'shall not on the whole be higher or more restrictive.'

There are essentially three issues. First, does a given structure of RIAs create a force for more or less liberal external trade policy? Second, is there an inherent dynamic of RIA formation which will lead to ever larger RIAs – perhaps even a RIA of the whole world, giving global free trade? And third, is there evidence that the presence of RIAs has assisted or retarded progress in the multilateral trade system?

An insight into the effect of the number of RIAs on incentives to set external tariffs was provided by Krugman (1993) who noted that if tariffs are set to improve member countries' terms of trade, then they will be lowest – and consequently world income greatest – in two opposite circumstances. One is when there is a single world trade bloc containing all countries, i.e., global free trade. The other is when trade policy is set by many small independent jurisdictions, each so small as to have no market power and no reason to deviate from free trade. Between these extremes each trading bloc has an incentive to use external tariffs to try and improve its terms of trade, suggesting that a situation of relatively few large trading blocs might be the worst possible outcome.

This line of argument has been criticized from a number of different angles. From the theory side, it should be recognized that tariff setting is a repeated game, so the incentives to cooperate, or to deviate from cooperation, need to be taken into account (Bond and Syropoulos, 1996; Winters, 1998). From the institutional side, it has been pointed out that article XXIV of the GATT expressly forbids RIAs from raising external tariffs. And from the empirical side, no evidence has been found to suggest that RIAs are in fact prone to set higher external tariffs than are separate countries (Foroutan, 1998).

What of the dynamics of RIA formation? Does adding a member country to a RIA increase the incentives for further countries to join, and will existing members be willing to permit

unrestricted entry? A number of researchers have argued that the incentives to join increase as RIAs become larger – a phenomenon termed 'domino regionalism' by Baldwin (1995). This may be because of perception of growing benefits of membership, or because of increasing costs of being outside. These costs can arise as outsiders' terms of trade may decline (the other side of the members improving terms of trade referred to in Section Trade Creation and Diversion). Perhaps more importantly, countries fear that firms may relocate, in search of the benefits of a larger market (evidence of foreign direct investment flows in Europe at the time of the Single Market Program suggests that this occurred, Baldwin et al., 1996). Another source of loss from nonmembership of RIAs is the risk of being isolated if a trade war occurs (Whalley, 1998).

Although these arguments suggest a growing demand for membership of RIAs, it is less clear that this will be matched by a willingness to accommodate new members, at least within existing RIAs. The most important tradeoff here is between the benefits of 'deeper' integration, and the difficulty of achieving this with larger memberships. Thus, while the EU has continued to enlarge, worries about the difficulty of accommodating new entrants impedes progress. An important contribution to the ideas on regionalism was made when the Asia Pacific Economic Cooperation (APEC) forum announced the principle of 'open regionalism.' Although this term has been given a number of quite different meanings, the key idea is that of open access, whereby the RIA announces that any country willing to abide by its rules may join. However, at time of writing, the idea remains to be put to the test, since APEC itself has yet to develop as a RIA. Overall, then, it seems that regional integration does create its own dynamic, attracting further countries to want to join. But there is no reason to believe that all such requests should be successful, or that the end of the process is more likely to be a single world free trade area than it is to be a number of competing trade blocs.

Finally, are there any reasons to believe that the presence of RIAs has facilitated or impeded progress in multilateral trade negotiations? The argument for impedance hinges mainly on finite government capacity. Investment of time and effort in regionalism reduces the capacity of governments to invest in multilateral negotiation. On the other side, it is argued that regionalism can help, by reducing the number of separate negotiators (since members of a customs union negotiate as a single body) – an argument that begs the question of how members formulate their common position.

Also, it is suggested that regionalism has proved valuable by providing 'laboratories' for trying new approaches to issues of trade reform, particularly on more difficult issues. As for the track record of RIAs and multilateral negotiations, views are again divided, although there is a view that fear of fragmentation into regional blocs provided a spur for successful completion of the Uruguay round of trade negotiations (WTO, 1995).

Conclusions

Joining a RIA is a major 'one-off' event for a country. It affects all aspects of the economy – goods prices, the structure of production, and income flows to different economic agents. Generalizing about the implications of such occasional and large changes is inevitably difficult. Nevertheless, research has established the circumstances under which gains or losses are more or less likely, and drawn out the implications of this for the design of agreements (World Bank, 2000). Future research needs to pay greater attention to strategies for developing countries, and the role of RIAs in assisting them to participate effectively in the world trading system.

Internationalization: Patterns in Business Firms

Ivo Zander, Uppsala University, Uppsala, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article reviews historical and contemporary patterns of how business firms extend their operations outside their country of origin. Addressing the 'why,' 'when,' 'where,' and 'how' of business firms' internationalization, it illustrates how over time traditional and incremental approaches to internationalization have evolved toward increasingly heterogeneous and rapid internationalization processes. Especially the emergence and internationalization of multinational corporations from the developing countries suggest ongoing and potentially far-reaching changes to the international business environment.

Introduction

Patterns are about regular and intelligible forms or sequences discernible in the way in which something happens or is done (http://oxforddictionaries.com). This article will be concerned with such patterns, specifically patterns in how business firms have been observed to internationalize, that is, extend their operations outside their country of origin and into foreign countries.

In a brief introduction to the article, it is useful to also consider the meaning of the rather amorphous concept of internationalization. While a firm's country of origin may be defined as the country in which it was incorporated and in most cases also carried out its first commercial activities, internationalization or the extension of operations into foreign countries covers a range of activities. These activities include the foreign traveling of firm founders and managers, the borrowing of foreign capital, the importing and exporting of products or services, but also the development of more extensive operations such as marketing, manufacturing, and research and development, which then typically involve various degrees of ownership of assets in foreign countries.

In other words, internationalization is a broad concept, which can only be partly covered in this article. The main emphasis here will be on the internationalization of business firms in terms of their efforts to either source, sell, or develop products and services outside their country of origin, and particularly but not exclusively on investments that involve some degree of ownership and control over foreign operations. Whenever the latter has occurred, it will be referred to as foreign direct investments and business firms referred to as multinational corporations (MNCs). Yet, as will be shown presently, ownership and control over foreign resources may not be a core or defining characteristic of internationalization, especially when it comes to the international expansion of contemporary business firms.

As an introductory roadmap, the presentation will focus on a set of questions which include the 'why,' 'when,' 'where,' and 'how' of business firms' internationalization (cf Welsh and Luostarinen, 1988). It will focus primarily on patterns as they have been observed and evolved over time, but also to a more limited extent explore the underlying drivers, consequences, or tangential issues as discussed in the vast international business literature (e.g., Jones, 1996; Dunning and Lundan, 2008; Dunning, 2009). Needless to say, the presentation can cover only a small proportion of the literature on each of the questions, and to every pattern of internationalization that is proposed there are surely contrasting and contradictory examples to be found. The main ambition has been to give an overview of the phenomenon, offering some select references that may serve as entry points into the specialized literatures as they have evolved over the past decades.

'Why'

The answers to this question may seem obvious, but over the past century and a half there have been some interesting shifts in the ways by which firms have decided to invest in foreign markets. As documented by Dunning (1983) and Wilkins (1988), early European and North American multinationals were looking to either secure the supply of inputs and raw materials necessary for their operations, or to expand the size of the market for their products. Securing the supply of inputs and raw materials appears to have been the dominant motive when firms in the mining, oil, rubber, agricultural, and food industries internationalized in the late nineteenth century, whereas market-seeking motives or the ambition to expand sales volumes came to the fore after World War II.

Both resource- and market-seeking motives reflect the desire to protect or enhance the profitability of the company, sometimes complemented by a host of other but in many cases secondary motives. Such motives include the desire to improve overall performance by locating and coordinating select business activities in foreign countries, which is sometimes referred to as efficiency-seeking behavior, or to monitor and interact with competitors in international oligopolistic industries. More peripheral motives include founders' and managers' desire to create international business empires, which may coincide with other ambitions that do not necessarily prioritize shareholder wealth and dividends.

Especially in the case of market-seeking internationalization, firm-specific advantages and unique products and services have been instrumental for developing the desire and confidence to go abroad, and also for overcoming the disadvantages or liabilities of foreignness that affect firms when they first enter specific foreign markets (Zaheer, 1995). Such firm-specific

advantages may be proprietary technology and knowledge about products or services, or any set of factors that allows the firm to offer products or services that are unique or particularly appealing in terms of their cost–performance relationship. In many cases, such firm-specific advantages and unique products or services reflect the structure and characteristics of local industry, so that internationalizing firms may serve as indicators of industries in which the home country has proven particularly successful and competitive. There is also much that speaks for the gradual development of firm-specific advantages that derive from the firm's presence in several countries and markets (Rugman and Verbeke, 2009), but these types of advantages will not be examined in detail in the current account.

Emerging New Motives

While the desire to exploit existing firm-specific advantages has been a consistent theme in firms' internationalization, the past decades have nevertheless seen what appears to be a shift toward internationalization aimed at uncovering new or additional firm-specific advantages. What have been referred to as asset-seeking investments (cf Dunning and Lundan, 2008) imply that firms engage in business activities in foreign countries not to exploit their already existing advantages, but instead to seek complementary knowledge, build new advantages, or compensate for competitive weaknesses by establishing operations in foreign locations. While some firms may be looking for expertise in select functions or parts of their value-adding activities (e.g., firms may establish design centers in locations known for being the sources of new consumer trends), others may buy their way into technological capabilities and products that offer different and better growth prospects than those associated with the company's current business portfolio.

In yet other cases, the establishment of foreign operations can be a way to learn about foreign market demand and more efficient management practices. Such motives have been observed particularly among emerging MNCs from developing countries, which by linking into the global value chains created by established MNCs, leveraging their resources in terms of technology, knowledge, and brand names, and engaging in concerted learning efforts have created increasingly broad-based advantages to compete internationally (Mathews, 2002a; Buckley, 2009). Ultimately, such processes may result in acquisitions of firms in developed economies to get first-hand access to technology, management, and marketing expertise, or to capture established brand names and networks of suppliers and distributors (Deng, 2007). In yet other cases, investments in developed countries have been motivated by the need to alleviate or circumvent institutional constraints in the home market (Luo and Tung, 2007). From this perspective, and while the exploitation of firm-specific advantages probably has remained the main explanation for firms' internationalization, internationalization may capture both exploitative and explorative ambitions of the expanding business firm.

'When'

It is clear that internationalization of various forms has been going on for centuries, but in the context of multinational firms that own, control, and actively manage their international investments broad-based internationalization efforts coincided with industrialization and started taking off in the latter half of the nineteenth century. The foreign direct investment activities of emerging and already established MNCs increased steadily from the late nineteenth century and onward, especially among firms from North America and Europe (Dunning, 1983). Internationalization activity then decelerated during the interwar period, only to pick up again cautiously in the two decades after World War II and then more forcefully over the decades leading up to the present (**Figure 1**).

Figure 1 Growth in outward foreign direct investment, select developed countries ($ billion). UNCTAD, 2013. http://unctadstat.unctad.org/TableViewer/tableView.aspx?ReportId=88.

Patterns of foreign direct investment activity have been intimately connected to general conditions in the international business environment (Jones, 1996). During the interwar period, political unrest and spreading nationalism gradually curbed firms' internationalization ambitions and in some cases resulted in either divestments or nationalizations. In contrast, the postwar integration of world markets and more liberal attitudes toward foreign direct investments resulted in an environment much more benign toward firms' internationalization efforts (Dicken, 2007). Reduced tariffs, improved means of communication, and lowered transportation costs have all contributed to MNCs' willingness and ability to establish more extensive and coordinated networks of geographically dispersed units.

It is also clear that business cycles of shorter duration affect firms' willingness to engage in internationalization activities. Generally, it has been found that peaks in the global economy come with increased international merger and acquisition activity, whereas periods of slowdown or decline have the opposite effect (**Figure 2**). Such changes in the global economy may also affect the relative attractiveness of different modes of foreign operation, for example, greenfield investments and foreign acquisitions (UNCTAD, 2012).

The Firm Perspective

An alternative approach to the 'when' question is to take the firm's perspective, asking at what time in its development it decides to become engaged in international operations. There is not so much systematic information about this issue, partly because it is difficult to establish a common definition of the start of international activities. There are, however, indications that the timing of firms' internationalization efforts has seen some shifts over time.

For many and probably most business firms, the search for requisite resources and especially markets for their products and services starts in their home country (Wilkins, 1986). This is where founding entrepreneurs discover and develop their business ideas, and also where business models are first tested out and perfected. This also implies that at the time of the first internationalization efforts most firms have reached a certain age and size, although there may be quite some variation across the two parameters. Especially among firms with small home markets and which operate in scale-intensive industries, international activities and sales can be expected to start comparatively early on.

One of the most significant developments over the past decades is the emergence of a new type of firm, which appears to internationalize from very early on in its existence. These are firms that have been given a variety of names, including born globals (Knight and Cavusgil, 2004) and international new ventures (Oviatt and McDougall, 1994). Drawing upon an increasing number of internationally experienced individuals and often found in the high-tech industries, they already from inception combine and coordinate international operations, including the raising of capital, manufacturing and sales, and research and development activities. As resources tend to be scarce in such newly established and rapidly expanding firms, internationalization also tends to employ alternatives to foreign direct investment and ownership of assets. These alternatives include technology licensing and alliances, or various forms of contractual arrangements for securing access to critical components or distribution of products and services.

'Where'

The 'where' question divides into two related parts, one that concerns the sources of internationalization activity – or countries from which internationalizing firms originate – and one that concerns the target countries.

For a long period of time, the greater part of internationalization activity was connected to firms originating from relatively advanced economies. Wilkins (1988: p. 11) summarizes the conditions that applied to the growth of MNCs at the turn of the nineteenth century: "The more industrialized, the more economically advanced the country, *ceteris paribus*, the more likely for it to be the headquarters for business abroad." Throughout the first half of the twentieth century and beyond, more than 95% of all foreign direct investments were accounted for by MNCs from the developed countries, including the United States, the United Kingdom, Germany, and France (Dunning, 1983). From the 1960s and onward, firms originating from Japan came to play an increasingly

Figure 2 Value of cross-border mergers and acquisitions (valued at over $ 1 billion). UNCTAD, 2009. World Investment Report – Transnational Corporations, Agricultural Production and Development. United Nations, New York, and Geneva.

prominent role in total foreign direct investment activities (Dunning, 2009).

From about the 1990s and onward, however, the sources of foreign direct investments have increasingly been found among firms from developing countries. While developing country MNCs have existed for a long time, historically their foreign operations have been associated primarily with low-cost and undifferentiated products, target markets consisting primarily of other developing countries, and only marginal relative proportions of worldwide foreign direct investment activity. Much of this has changed during the past two decades, both in terms of modes of operation and overall impact on worldwide foreign direct investments (**Figure 3**). These are firms that will be returned to presently when discussing the 'how' question, as their entry into the world economy seems to have been made possible by strategic and organizational innovations well adapted to the international business environment at the opening of the twenty-first century.

The second part of the 'where' question concerns the countries that are selected as targets for internationalization and foreign direct investment activities. Generally speaking, while outward flows of foreign direct investments have traditionally been concentrated to a limited number of developed economies, the targets for internationalization activities and investments have been more diverse, with a significantly greater proportion accounted for by developing economies (Dunning and Lundan, 2008).

Patterns of Incrementalism

From the individual firm's perspective, it appears that the extension of the geographical scope of operations typically proceeds incrementally. In the early days of internationalization, starting in the late nineteenth century, internationalizing firms thus extended their activities into nearby or otherwise related countries (Dunning, 1983). Geographical and cultural proximity, or ties from periods of colonization played an important role in determining the location of the first investments of expanding MNCs. Such tendencies have been traced to the concept of 'psychic distance' (O'Grady and Lane, 1996), broadly defined as anything that prevents the flow of information between countries and creates barriers to learning about business conditions in a specific foreign market. Some of its main components include geographical distance and differences in culture, language, and political systems.

Geographical and other types of proximity indeed appear to underlie a consistent pattern in which MNCs prefer to trade and invest selectively in what may be referred to as 'close' countries (Dicken, 2007; Dunning and Lundan, 2008). For example, US multinationals have had a much stronger propensity to invest in Mexico and Latin America than their European and Japanese counterparts, and a major part of Latin American and Asian foreign direct investments have been made elsewhere in those regions. This, of course, does not preclude other investments in what would be more 'remote' countries, and there remains quite some variation in preferences across countries and individual firms, particularly in the case of born global firms or international new ventures. Nevertheless, the overall pattern indicates that the idea of truly global corporations in terms of operations and foreign investment activities is limited to a small number of cases (Rugman, 2001).

'How'

One major assumption about how firms internationalize has been that they commit resources to foreign markets incrementally, and only as uncertainty about local business environments is reduced and the investing firm gains access to wider opportunities in the local environment. The typical development of activities in any given country would go from initial exports or independent agent relationships to more committed forms such as wholly owned sales subsidiaries, and ultimately to wholly owned subsidiaries that involve more advanced functions such as manufacturing and research and development (Johanson and Vahlne, 1977).

Figure 3 Distribution of outflows of foreign direct investment. UNCTAD, 2013. http://unctadstat.unctad.org/TableViewer/tableView.aspx?ReportId=88.

While the tendency to invest incrementally and cumulatively has been documented across a number of country settings (Welsh and Luostarinen, 1988; Johanson and Vahlne, 1990), developments over the past decades may have reduced its general validity. Some of the main influencing factors include more generally available information about the international business environment and more internationally experienced individuals, managers, and firms. For example, improved information and a sense of greater familiarity with foreign markets may partly explain why the proportion of greenfield ventures relative to acquired units declined from the turn of the nineteenth century and until the 1960s, and why since then mergers and acquisitions have become a favored but fluctuating means of foreign expansion, especially among MNCs from the developing countries (UNCTAD, 2012).

Other factors that may cause a departure from incremental and cumulative investment processes include industry-specific conditions and any firm-specific strategies for international expansion. It could also be added that through government intervention some countries may not be open to all types of investments by foreign firms, making it impossible for internationalizing firms to utilize otherwise preferred modes of local operations (e.g., China upheld strict restrictions on wholly owned foreign direct investments until the early 2000s). While many companies could thus be expected to commit resources to foreign markets in an incremental and cumulative way, individual cases may display significant deviations from the general pattern.

Internationalization at the Functional Level

Some investigations have looked at patterns in how firms internationalize various parts of their value-adding activities, including manufacturing and research and development activities. Some early attempts to describe and explain systematic changes in the nature of involvement in foreign countries emphasized the local origins of new product ideas and how throughout the product cycle product standardization causes a shift of manufacturing operations from the country of origin to foreign countries (Vernon, 1966). While the formation of well-established MNCs and increasing homogenization of the world's economies have altered some of the model's validity, the tendency to locate standardized manufacturing and other activities to low-cost countries has remained a significant feature of the well-established MNCs.

Starting in the late 1970s, the search for lowered costs of standardized manufacturing and other activities gave rise to a pattern by which well-established MNCs offshored and sometimes also outsourced select parts of their value-adding chains. Enabled by the rapid developments in information technology, much of these offshoring initiatives emanated from the United States and found their home in India, although over time patterns tended to become more geographically diverse. Offshoring has also come to include more advanced operations such as engineering and research and development (Lewin et al., 2009), perhaps reminiscent of the incremental and cumulative processes identified in firms' overall internationalization processes.

A second pattern in the internationalization of individual value-adding activities is the gradual increase in the amount and proportion of research and development carried out in foreign locations (UNCTAD, 2005). While asset-seeking investments are part of the explanation, the observed increase is probably in large part explained by independent and cumulative growth of foreign subsidiaries (Blomkvist et al., 2010). This growth appears to follow a pattern by which over time individual foreign units become more embedded in their local business environments – that is, forge closer contacts with existing suppliers, customers, and other local actors – and ultimately develop the capability to create and commercialize products and services that are sold locally and in some cases internationally as well. Such developments would then reflect a gradual deepening and extension of business activities carried out in individual foreign locations, although there remains quite some variation across types and levels of sophistication of foreign establishments.

New Currents

The general expectation about incremental internationalization and expansion of foreign operations disguises a more diverse pattern of internationalization among MNCs of more recent origin, as first documented in the context of firms from the Asia-Pacific region (Mathews, 2002b). Such firms may undergo accelerated internationalization by simply accessing and leveraging already existing resources in the global business environment while not necessarily becoming engaged in extensive ownership of these resources (Mathews, 2006; Mathews and Zander, 2007). They may not even start out with a distinctive technological edge or firm-specific advantage, but through technology acquisitions, alliances, and concerted learning efforts catch up with or leapfrog established competitors. Seen from a different perspective, such firms utilize already existing resources in the global business environment to identify and rapidly pursue business opportunities that have been either overlooked or on account of negligence and organizational heritage left unattended by incumbent firms.

Conclusions and Future Developments

Various forms of internal business activities have been carried out for centuries, and it is clear that in the long-term perspective there have been discernible patterns of internationalization, which fall outside of the scope of the current account. The patterns of internationalization that have been outlined here pertain to developments from the late nineteenth century and onward, and concern the operations of what could be described as modern MNCs, or those that engage in some form of ownership and coordination of geographically dispersed resources and operations.

At the fundamental level, patterns of internationalization reflect a set of processes that have remained more or less unchanged over time. As individuals discover new business opportunities they seek to exploit those opportunities in the best possible way, which includes attempts to protect and secure the new business and extend sales to markets as large as possible.

The exploitation of new business opportunities is accompanied by imitation and emerging competition, necessitating concerted efforts to control costs and to continuously upgrade existing products and services. In some cases, the continuation of profitable business may also require the development and entry into significantly new product and service offerings. In all of these undertakings, the international business environment offers potential advantages for expanding business firms, and it is thus not surprising that as a group they have embraced these possibilities and in many cases reacted in fairly similar ways.

In the expansion of international operations, whether upstream or downstream in the value chain, firms should be expected to favor locations where business contacts have been established, and also those locations that can be accessed, controlled, and coordinated with relative ease. From that perspective, and considering significant limitations to the extent individuals may move about in time and geographical space, internationalization patterns that embrace and build on the familiar and accessible are likely to persist also in the foreseeable future. Accordingly, there will also remain a fundamental tendency to approach and incorporate locations that are perceived of as more distant only in the later stages of the expansion of international operations. As firms face resource constraints in the short run, it seems equally likely that by and large investments in foreign locations are made incrementally and cumulatively.

This said, since the mid-twentieth century there have no doubt been considerable and perhaps accelerating changes in the preconditions for initiating and carrying out international business operations. From early on, through traveling, international education and later on involvement and careers in internationalized business firms, the individual can now increasingly establish and maintain a relatively broad network of international contacts. These contacts can then be used not only for the discovery of new business opportunities, but also for the expansion of new businesses in the international domain. Other enabling factors that come into play are easier access to knowledge and technology (e.g., through the Internet, commercially available databases, and markets for technology), improved and more rapid means of communication and transportation, and the harmonization of institutional conditions and legal systems to make different countries and business environments appear increasingly similar and 'familiar.'

There are thus good reasons to expect locationally determined and incremental patterns of internationalization to give way to increasingly diverse ways of creating and exploiting new business opportunities. This then involves expectations about a growing proportion of various types of born global firms or international new ventures, and also about firms originating from developing economies that find new and in many cases innovative ways of responding to previously unexplored business opportunities. It could be added that such firms have probably existed longer than their relatively recent discovery in the academic literature suggests, but as of yet there are few sources that can firmly document how the relative proportions of different types or 'species' of firms have evolved over time.

Old and New Patterns of Internationalization

It may indeed be useful to make a distinction between patterns of internationalization that apply to the old and by now well-established MNCs, and those that apply to multinationals of more recent origin. The now well-established MNCs typically came about during times when knowledge and the individual's experiences were location-bound, giving rise to patterns of internationalization characterized by a gradual expansion from a relatively well-defined point of departure. In contrast, MNCs of more recent origin would be less tied to local conditions and experiences in the identification of new business opportunities, and through processes of linkage, leverage, and learning also be able to rapidly access and utilize a larger set of geographically dispersed resources (Mathews, 2002a). The opening up of previously protected and regulated markets such as China,

Figure 4 Growth in outward foreign direct investment, select developing countries ($ billion). UNCTAD, 2013. http://unctadstat.unctad.org/TableViewer/tableView.aspx?ReportId=88.

India, and other developing economies offers additional opportunities for new firms to enter into markets that have traditionally been neglected by many old-time MNCs. The overall conclusion would be that apart from assuming a more prominent position in the population of different types or species of MNC, recently established MNCs will display internationalization patterns that are increasingly diverse in terms of origins and characteristics and also unfold more rapidly than before.

What seems to be beyond dispute is that new firms originating from the developing economies have now started to account for an increasing proportion of all outward-bound foreign direct investment activity, and at a pace that surpasses that of MNCs from the developed economies (Figure 4).

The pattern which has been observed over the past three decades may signal a significant reshaping of the competitive landscape, and also the advent of some still unexplored patterns in the interaction and international activities of established and newcomer firms.

Abstract

The increased use of the Internet since the late 1990s has had a large impact on how arts and culture products such as films, books, cds, museum exhibitions, etc., are produced, distributed, acquired, and received. This article aims to discuss some of the most relevant developments in the study of the Internet's relation to arts and culture from a social-scientific perspective. It focuses on (1) processes of producing and distributing culture (material production); (2) ways in which cultural products are classified and legitimated (symbolic production); and (3) behaviors and perceptions of cultural audiences.

Introduction

The increased use of the Internet since the late 1990s has had a large impact on how arts and culture products such as films, books, cds, museum exhibitions, etc., are produced, distributed, acquired, and received. The World Wide Web has shortened communication lines between companies and between persons, enabling global contacts to strengthen and cultural exchanges to increase. How increasing usage of Internet and other new media continues to shape our social life has been among the fastest growing topics in communication research in the past decade. The consequences for the domain of arts and culture are in some respects much debated (e.g., the controversies of illegal downloading), yet in other respects rather taken for granted (e.g., the decline of cultural authority).

This article aims to discuss some of the most relevant developments in the study of the Internet's relation to arts and culture from a social-scientific perspective. Although the focus will mainly be on those cultural artifacts and events which are classified as forms of 'art' – be it highbrow, middlebrow, or popular – by legitimate experts in society, one of the conclusions of this article will be that on the Internet also new, less classifiable cultural genres emerge. Similarly, the boundaries of the Internet are not always clear, as its increased usage is accompanied by many related new media and *information and communications technologies* (ICTs) (e.g., hardware devices such as cell phones and iPod and software) which can also be objects of study. This overview aims to discuss three aspects of cultural fields in which the influence of Internet is observed: processes of producing and distributing culture (material production); ways in which cultural products are classified and legitimated (symbolic production); and behaviors and perceptions of cultural audiences. In doing so, we draw upon various research perspectives, which will first be introduced in Section Research Perspectives. This article cannot claim to be exhaustive, but at the same time we point out that large parts of the territory are still unexplored. Not only does much of the current literature have a much broader take on 'culture,' most of the work that does address arts and culture in a more strict sense remains largely theoretical or practical, but yet lacks empirical backup.

Research Perspectives

Internet has revolutionized (re)production, distribution, and consumption of media materials in at least three important ways. First, its networked structure allows Internet users – regardless of their status or profession – to connect directly to almost all other Internet users and exchange media content without the intervention of professional gatekeepers. Second, Internet has incorporated technology that is both available and accessible for many Internet users, which can be applied to create, edit, upload, and download all types of text-based and audiovisual content. Thirdly, Internet is increasingly seen – particularly by the most recent birth cohorts – as the principal medium to gather information on or access to culture and entertainment at the expense of print media, radio, and television. Losing the monopoly to mass production and distribution of cultural goods and weakened control over information flows have both economic and symbolic implications for cultural producers as well as consumers. At the core we find the hierarchically ordered 'cultural field' in which professionals engage in cultural production through highly institutionalized practices and logics (Bourdieu, 1993) being challenged by alternative practices. Scholars have begun to theorize and, to a lesser extent, empirically study these developments in various ways.

Within communication research, we find three important perspectives. Digital inequality studies are concerned with audiences and users of ICT and Internet – more particularly, who have access to new media and who are most likely to actually use such media for social participations (e.g., in the realm of culture). Increasingly, however, notions of 'audiences,' 'users,' and 'consumers' are contested for dismissing the blurring of boundaries between consumers and producers. In particular, work on peer production – or user-generated content – details the work of 'prosumers': nonprofessionals who create cultural content online which sometimes invokes semi-institutionalized fields on its own, such as the blogosphere (Bruns, 2008). These studies also showed that despite the wide reception and application of this user-generated content, only a small segment of the population is involved in its active creation (Van Dijck, 2009). A third and related scholarship analyses computer-mediated communication and

its effects on behaviors and attitudes. While often not particularly concerned with culture, it has produced relevant insights in how more or less institutionalized forms of communication (e.g., online reviews of amateurs vs professionals) influence recipients' perceptions. The significance of expertise and authority is among the focal points – particularly in studies on how 'collective knowledge' is produced on the Internet (e.g., online encyclopedia Wikipedia).

Internet's economic implications with regards to arts and culture tend to diverge in two main directions: consequences for business models and for marketing strategies. Media economists (but also other publicists) have started to analyze how the cultural industries have (not) adapted to changes in the way cultural products are acquired through online outlets (e.g., illegal downloading, web stores).
